It will be observed that in the few examples here introduced the comparison is made in perspective. It is distressing to watch a designer arranging main masses in elevation, and also to remember the "no perspective" (!) law of the architectural competition. It is very easy to see, and we commonly and too frequently do see, an elevation introducing, say, centre and wings, plainly designed on the principles of the decorator or fret-worker—artists in the flat—two-dimension design; but it is sufficiently evident that the labour is in vain, the perspective—the real, true, and only possible effect of three-dimension (solid) design—upsetting the whole arrangement. No doubt but that the tameness—even in ordinary perspective, not to mention that of piquant sharpness—so general, is the result of elevational designing. An elevation is but an algebraical expression, as it were. One effect is imaginary, the other real. By courtesy we may allow that a cube has eight solid angles; in reality—for the purposes of the architect—it has, when on a large scale, two inoffensive obtuse angles and one very striking, immensely pugnacious, dominant solid angle.

A natural result of elevational design is to overcrowd "work," as in a cornice, where that which shows as, say, a dozen lines on elevation, appears in perspective as possibly twenty or more lines, if the margins of narrow and other shadows may be so designated. It seems sufficiently plain that, if the effect was good in elevation, something would be out of harmony in perspective. Not necessarily, perhaps, but the supposition is justifiable.

(To be continued.)

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

A MEETING of the Institute of Architects was held on Monday, March 29, at Conduit Street, W., Mr. Ernest George, President, in the chair.

The Secretary announced the decease of Mr. Alfred Henry Paget, elected Associate in 1870 and Fellow in 1892. Mr. Paget was a past president of the Leicester and Leicestershire Society of Architects, and represented that Society on the Council of the Institute during the years 1892-3.

Mr. M. H. Spielmann delivered a lecture, illustrated by a long series of lantern slides, entitled:—

British Sculpture.

He said his aim throughout would be to show the good in things without dwelling unnecessarily on what was indifferent and bad. His lecture would be an object-lesson rather than one on theory, and an endeavour to point out the remarkable position to which in latter days British sculpture had attained. He was therefore concerned with the aims of the school which had arisen in Great Britain within the memory of some of those whom he was addressing, and he would place before them certain facts in relation to the art which had been overlooked by the public. Since 1875 or thereabouts a great change had come over British sculpture, a change so revolutionary that it had given a new direction to the aims and ambitions of the artist, and had raised the character of the art to a level beyond expectation. Sculptors awoke to an appreciation of plastic and glyptic beauty, but they were without a past of their own to inspire them; there was no national tradition, and they had to commence at the very beginning. Lord Leighton, Alfred Gilbert and, in a lesser degree, Onslow Ford, were the influences of that new conception of sculpture. It was difficult to realise how bad it was sixty years ago. Men had begun to rebel against what they saw, and asked if it was art. But the ignorance of sculpture was confined to no class; indeed it was found, unhappily, in the highest official class—the Government circle—where appreciation was to be so earnestly desired. Ruskin had said:—"The only way for a nation to obtain good art was to enjoy it." The safe way, continued the lecturer, to obtain bad sculpture was to appoint a Minister of Fine Arts from among politicians, for nearly all patronage of that kind went to encourage bad art. They would remember the scorn which was levelled at Mr. Norman Shaw's New Scotland Yard at the time of building, one of the finest modern architectural works. The most mischievous ignorance was that shown by committees formed to consider the erection of public statues. They crippled and baulked the efforts of the artist by their irritating interference, and the lecturer went so far as to suggest that Stevens, Barry and Wilkins were driven into their graves by the treatment they had been subjected to at the hands of committees. People should remember that they ought to do nothing which would disturb the delicate organisation of the artist who was at the mercy of his inspiration, which was the flower of his artistic emotion and the very essence of his work. The committee of a musical festival did not interfere with the composer, and sculpture was no less a matter of harmony and science. Besides knowledge there was taste, and taste must be trained for fear it was corrupted by the false and meretricious in art, which was more dangerous than the merely incompetent. Bad taste was worse than no taste at all, for no taste could be educated, but bad taste was vicious already. Bad taste might be clever and tricky, and they saw the reflection of it in the popularity of much Italian work exposed in salerooms. Chief among the characteristics of the modern British school was the effort towards such realism and picturesqueness of treatment as did not detract from the dignity of the conception. The public, of course, welcomed any approach to what was pictorial, but sculpture primarily should represent ideas and not things. Michel Angelo had said, "The nearer painting is to sculpture, the better it is; the nearer sculpture is to painting, the worse it is." The present aim of sculpture was to give life without undue realism, a suggestion of reality shrouded in poetry and grace; yet there must be symbols of the ideas to be personified. Those symbols were loved for their beauty and significance, for they were of the essence of sculpture, the types of humanity and the representations in human form of poetic conceptions. They were therefore an irresistible attraction to every sculptor, who in dealing with ideal conceptions avoided the draped figure, and so escaped in one direction subjects of actuality and of the present day. As Lessing pithily said in the *Laocoon*, "The aim of art is beauty. . . . Clothes are the outcome of necessity—and what has art to do with necessity?" And it was not only beauty of form that attracted the sculptor, but beauty of movement for its own sake, as developed in the play of muscle, joint and structure and of expression. All that was concealed by drapery. At the same time, in drapery properly managed elegance and dignity were inherent, but it should be treated severely. It was not surprising that so subtle an art as sculpture was little understood, for the eye was ever affected more by colour than by form. Painting was frankly illusive, and sculpture to the unthinking appeared to be imitative, yet it was nothing of the kind. A sculptured model had to be idealised, or the result would be commonplace, and thus, while the painter could take any theme, the sculptor was severely and chastely restricted. Sculpture was the expression of form without colour, without atmosphere, without tone, and the introduction of colour therefore condemned itself. The more a statue looked like a real man, the less it was like sculpture and the more like waxwork. Until Alfred Stevens did so, scarcely anyone thought of instilling real life and blood into clay and marble. And what life it was he realised! He was no copyist, but entirely personal. Stevens was in the right sense unconscious of his greatness; and had not the accident of an open competition made his genius patent to the world, he might have gone on to the end of his days teaching, designing fenders, pots and fire grates and other details, with an occasional portrait. One of the secrets of his success was his knowledge of construction and his feeling for architecture, which helped him to treat sculpture with fine decorative effect.

Mr. Spielmann then showed in chronological order by lantern views some of the work of sculptors of the British school. The first slide was an illustration of Stevens's sketch model for the Wellington Memorial in St. Paul's. The lecturer explained how the composition would be thrown

Digitized by Google

out of scale by the addition of the horse and figure. Thomas Woolner, who maintained that elevation which brought him applause for his "Virgilia lamenting the Banishment of Coriolanus," did not attempt a truly realistic subject till towards the end of his career, and then failed of complete success. Baron Marochetti tried to introduce a more modern feeling, and his "Richard Cœur de Lion" at Westminster evoked great enthusiasm. Sir Edgar Boehm was on the whole more successful, but unhappily his best-known work in London, the "Wellington Memorial," was cold and empty, though possibly correct enough. Foley, who at first was all for "the unities" and "a pure style," as he claimed in his later years, threw his previous contentions to the winds when his epoch-making "General Outram" reminded the public that monuments need not be staid to dulness. Then came Armstead, the crowning merit of whose work was its unornamental character, its unusual dignity, bigness and sense of style. George Lawson, too, had a genuine sense of style, and just escaped general recognition as a fine sculptor. He belonged to the Scottish school. His "Motherless" was a group admirably Scottish in sentiment, full of pathos and free in handling, yet almost too pictorial for sculpture. His best work was full of distinction and free from trick or trifles. When Mr. Brock went to London in 1866 he entered the studio of Foley; but he soon felt the foreign current, and, brilliantly rebelling against his friend and teacher, he was courageous enough to modify his style when it was already formed and his career well assured; and, so developed, he had left his master very far behind. The ideal work that marked the transition was "The Moment of Peril"—a fine scholarly group, soon to be surpassed in technical quality and refinement of taste. How great was the change might be seen in "The Genius of Poetry"—graceful and reposeful where the other was violent in action and passionate, and sculpturesque where that was pictorial, or at least anecdotal. But a higher point was reached in "Eve," so touching in attitude and sentiment—a fair, shamed woman, purposely not endowed with that conventional perfection of beauty commonly attributed to the First Mother—more exquisite in feeling than in person, with her head bowed with the weight of remorse. In portraiture Mr. Brock had similarly excelled. Sir Charles Lawes-Wittewronge had spent his life in producing a very few works of high ambition. He was a champion of the architectonic note in sculpture, and was always strong and healthy in his work with good robust character. Mr. Hamo Thornycroft with "Teucer" reached the high-water mark of his early career. In the great national memorial to Mr. Gladstone in the Strand they had the *magnum opus* of Mr. Thornycroft in elaborateness, if not in quality. Mr. Havard Thomas obtained his following by his ideal work "The Slave Girl" and "Lycidas." Onslow Ford, who was lost to English art before he had passed the middle age, as a skilful portraitist whose heads were speaking likenesses, always showed the least common aspect of the sitter, and few in this country had excelled him either in skill or taste. In 1877 Lord Leighton produced his "Athlete struggling with a Python." No work of modern times made a greater stir on its appearance than that group, modelled by a painter, which would have done honour to the ancients. Great, however, as was the sensation made by Leighton's sculpture, and great as was his place in British art, the master seemed to have no direct follower or imitator among the younger men. Mr. John Swan had specialised a particular class of subject, for the most part studies of animals, mainly the *felidæ*. Mr. Harry Dixon was no less enthusiastic as a student of animal life. In Mr. Alfred Gilbert they had an artist who stood as one who had preached in his work a great movement, and in less than a decade effected as much as any other the salvation of the British school, and had influenced quite as much as Dalou or Professor Lantéri many of the young sculptors of the country. Harry Bates, in the short life during which he laboured, did splendid service to English sculpture and sculptors. In striking contrast with Bates was Sir George Frampton, in whom they had one of the most versatile and original artists of the day, thoroughly in the "new movement" which he had done so much to direct. Mr. Alfred Drury sought the graceful, the placid and the harmonious, and in his view of art cared little for vigour, passion, or anatomical display. Mr. Pomeroy was one of the most brilliant of the younger men. His individuality and mastery might fairly well be seen in the work, the commission for which he won, for the centenary "Statue of Robert Burns" for Paisley. Mr. Albert Toft's most elevated and sympathetic work was "Mother and Child. Professor Edward Lanteri had produced many admirable works on his own account. Mr. Goscombe John, as a student, established a reputation for feeling in his work, but he soon matured into something far higher and more admirable in the austere figure of St. John the Baptist. Mr. Bertram MacKennal's pediment for the offices of the Local Government Board in Parliament Street was, so far as the lecturer knew, the best work of its kind in England. Mr. Fehr was a sculptor from whom they might expect more and better work than they had yet had. Mr. Colton showed a Parisian flavour in some of his work, but he was endowed with so strong an individuality and possessed such a true power of design and sense of style that they might regard him as among the ablest leaders of the younger men. There were many other sculptors who were making a name—Mr. David McGill, Mr. Macgillivray of the Royal Scottish Academy, Mr. Derwent Wood, Mr. Garbe, and Mr. Albert H. Hodge. The highly original work of the last-named required, said Mr. Spielmann, a lecture to itself. It would have been observed, said the lecturer, that several of the most admirable sculptors had been trained as painters—Alfred Stevens, Mr. Swan, and Lord Leighton. But, excluding Alfred Stevens, none of all the sculptors who had been mentioned surpassed in power their greatest artist, George F. Watts, who as a sculptor claimed all their respect and enthusiasm. The half-a-dozen pieces of sculpture of Mr. Watts placed him very high indeed among the world's finest sculptors of the nineteenth century—high among the sculptors of all times. In conclusion, the lecturer asked, Did not the work of the grand old man—who in his eighty-seventh year was working upon one of the masterpieces of his life, the statue of Tennyson, set up in Lincoln—mark for them the true standard and point out the way for the younger sculptors?

Mr. W. GOSCOMBE JOHN, R.A., who proposed a vote of thanks to the lecturer, said sculptors would be delighted with the remarks they had heard from Mr. Spielmann. It was uncommon to hear anybody lecture about sculpture, and more uncommon still to hear anyone who understood it. Mr. Spielmann had gone to the problem with sympathy and knowledge, and the kind of knowledge very rarely met with outside the technical ranks. Most arts, said the speaker, were difficult to talk about among the uninitiated, and perhaps the most difficult of all were architecture and sculpture. There were so many things connected with the technical part, and to the outsider it was almost impossible to know what was the result of pure technique and what was the result of sentiment, and hence criticism was often unreasonable and at fault. There were many points in the lecture which started a train of thought. One of the most interesting was the origin of all that had taken place during the last thirty years, and they felt that Lord Leighton was perhaps the man who had most to do with the improvement through his "Athlete struggling with a Python."

Mr. W. COLTON, A.R.A., seconded the vote of thanks, and remarked that sculptors as a whole were greatly in want of spokesmen. He felt we were a very diffident race, and that sculpture in England was really in need of a great many spokesmen. It had been struggling for some years to become a school of sculpture, if he might say so, and perhaps it had hardly arrived yet at the time when it could walk without a nurse. He felt that Mr. Spielmann was the only spokesman they had to-day who really loved sculpture for sculpture's sake, and who was not led away by eccentricities. A mist seemed to have come over their intentions, and there was a curious craze at the moment for mutilation in sculpture. It was extraordinary, and they saw it in good exhibitions where many exhibits were a portion of the human figure—arms almost alone, heads split into sections, every possible mutilation. All these fractions of figures were really supposed to be very artistic and very fine; of course, they were simply eccentricities and were not fine work in any way. They were a cheap way of doing sculpture and a form in which anybody could succeed, so that he felt they were in need of spokesmen like the lecturer to properly point out the beauties of their art. They must try to put under foot unfriendly criticism, for if sculpture was to succeed it must be described in a friendly spirit.

Mr. H. H. STATHAM supported the motion, and said sculpture was the art for which he had the greatest passion, and he considered it the most intellectual of all the arts. He was old enough in regard to the progress of English sculpture to remember the whole rows of busts with realistic effects which were to be seen at the Royal Academy, but how different it was now. He was afraid that sculpture never could be a popular art, because it was essentially an abstract one. Mr. Spielmann had referred to the fountain near the Serpentine as an admirable piece of work, but the speaker thought its quality was not always appreciated, for he had

Digitized by Google

sought opinions upon it and had been told that it was a queer and ugly thing. It seemed to him that the great object of sculpture in its highest representation was to present some abstract thought in an abstract way, and sculptors used the figure not merely as an imitation of nature, but to express an abstract idea. In regard to the difficulty of dealing with dress, it had occurred to him that completely costumed figures could be dealt with better in bronze than in marble, as the material seemed to lend itself much better to the purpose. Then he had been struck, too, with the way in which the French very often got over the difficulty in costume of men by simply representing the bust on the head of a stele, surrounding it with abstract figures symbolic of traits in the man's character.

Mr. GOSCOMBE JOHN said all sculptors were agreed that bust portraits offered the best means of avoiding the difficulties of treating men's dress in sculpture, but English committees generally controlled the commissions for such work, and they would have the whole man—frock coat, boots and everything—and that was the reason why so many of our monuments were uninteresting.

ILLUSTRATIONS.

ITALIAN HOSPITAL, QUEEN SQUARE, W.C.

THE hospital was opened by His Excellency the Italian Ambassador on behalf of the King of ITALY, who presented Madame ORTELLI with a gold medal surrounded with diamonds (specially designed) in commemoration of the event. The façade was designed to be executed in Portland stone and red brick. The dome which surmounts the semicircular staircase in Devonshire Street is covered with lead. The basement is devoted to the servants' department, kitchen, larders, store-rooms, servants' hall, linen-room, heating chamber, washhouse, post-mortem room, and a vaulted mortuary under the roadway. The ground floor consists of entrance hall, board-room, secretary's, house surgeon's and porter's rooms, operating room, with accident ward adjoining, semicircular staircase with patients' lift in the centre. The out-patients' department is shut off from the hospital, and consists of waiting room, with separate entrance and exit, physician's, surgeon's and registrar's rooms, dressing room and pharmacy. The first floor is devoted to male patients, and consists of a ward for fourteen patients, smaller ward for four, and four single wards for special cases, with two detached sanitary blocks containing bathroom, lavatories, water-closet and slop-sinks. The staircase is detached from the wards by cross-ventilated lobbies. Opposite the staircase is the nurses' duty-room, fitted with hot closet, sink, cupboard and flap table, with food lift outside. The second floor is devoted to female patients, with a ward for eight, smaller ward for four, two single wards for special cases, children's ward and an isolated ward disconnected by a corridor open to the air. Sanitary blocks and duty-room, lifts, &c., the same as on the first floor. The top floor is arranged for the nursing sisters, and contains dormitory, sitting, dining, sick, workrooms and detached sanitary block. Two outside unenclosed lifts are provided to every floor for coals, dust, soiled linen, &c. One of the roofs is used as an airing ground for patients, with a covered shelter. The chapel is at the top of the staircase, under the dome. The staircase and floors are fire-resisting throughout. The ward floors are of oak in narrow widths, grooved and tongued, secret nailed and wax polished. The building is warmed throughout and lighted by electricity. This hospital is the cheapest erected in London. It has fifty beds costing 300*l.* per bed. The work has been executed by Messrs. HOLLOWAY BROS., of Belvedere Road, from the designs of Mr. THOMAS W. CUTLER, F.R.I.B.A.

VICTORIA STATION, S.-E. AND C. RAILWAY.—PRINCIPAL FRONTAGE, FACING FORECOURT—WILTON ROAD FRONTAGE.

THE accompanying illustration shows the principal frontage facing the station forecourt, and forms part of the new works now carried out at this station by the South-Eastern and Chatham Railway Company's managing committee. The works comprise a frontage of 165 feet to the station yard and 200 feet to the Wilton Road. Part of the site was once occupied by a canal basin, consequently a reinforced concrete raft 6 feet thick was constructed under the main portion of the building—that is, to the whole of the station yard frontage and extending along the Wilton Road for a distance of 80 feet. The new accommodation includes a restaurant on the first floor 160 feet by 38 feet, and one in the basement measuring 100 feet by 56 feet. The two frontages are faced with Portland stone; the plinth is in Cornish granite fine axed. The roof is covered with Welsh green slates laid in graduated courses. The buildings have been executed under the control and supervision of Mr. PERCY C. TEMPEST, the engineer to the managing committee, and Mr. W. J. ANCELL, architect, of Staple Inn. The elevations have been designed and detailed by Mr. ALFRED W. BLOMFIELD. Messrs. HIGGS & HILL were the contractors for the work. The sub-contractors were as follows:—Stone carving, including figures, HY. CHAS. FEHR; awning roofs and signs, Messrs. PREST, TEALE & Co.; staircase window, E. J. PREST; constructional steelwork, Messrs. M. T. SHAW & Co.; electric lighting and fittings, Messrs. STRODE & Co.; sanitary fittings, Messrs. ADAMSEZ & Co.; marble wall decorations, Messrs. H. J. JENKINS & SON; wood block flooring, the Zeta Wood Block Flooring Co., Messrs. ARTHUR JEFFERISS & Co.; lead glazing, Messrs. JAMES & Co.; mosaic floors and wall lining, Messrs. DIESPEKER & Co.; floor tiling in kitchens, Messrs. CANDY & Co.; wall tiling, Messrs. DOULTON & Co., Rust's Vitreous Mosaic Co.; fibrous plaster, Messrs. MARSHALL & Co.; gates, The Bromsgrove Guild; ironmongery, Messrs. COLLEDGE & BRIDGEN; metal panels, Messrs. JONES & WILLIS; lifts, Messrs. WAYGOOD & Co.

ST. GABRIEL'S COLLEGE, CAMBERWELL.—DETAIL OF MAIN FRONT.

THE view shown is the centre part only of a long main front. This part of the building was completed in 1901. The materials are Portland stone, red brick, and rough-cast. The latter is somewhat of an innovation in a public building, St. Gabriel's being a training college for women teachers in elementary schools. But it is found in practice, as was anticipated by the architect, that every three years the building looks beautifully fresh with its new coat of colour-wash, and, in London, this is no small gain at a very small cost. The statue of St. Gabriel over the entrance is by Mr. H. C. FEHR. The builders were Messrs. J. GARRETT & SON, Balham Hill, S.W., and the architect Mr. PHILIP ROBSON, of Westminster.

EASTBOURNE INSTITUTE.—EAST ANGLE.

OUR description of this building given on p. 81 (January 29) need only be supplemented by saying that the view given to-day is that of the east wing and one entrance to the art and secondary schools, on the first and second floors. The architect was Mr. PHILIP A. ROBSON, A.R.I.B.A., 9 Bridge Street, Westminster.

AUSTRALIAN CITIES IN THE MAKING.—PRINCE STREET, GRAFTON, N.S.W.

SEE article on "Australian Suburban Architecture," p. 234.

A Meeting of the Notts standing joint committee was held at the County Hall, Nottingham, on Saturday. The county surveyor reported that official sanction had been given for a new police station at Sutton-in-Ashfield, but the plans for Mansfield had been sent back for minor alteration. The Mansfield scheme was estimated to cost 2,500*l.*, and the Sutton-in-Ashfield one 3,000*l.* Mr. Hooley also submitted a detailed report of the expenditure necessary in rebuilding the part of the shire hall recently destroyed by fire. The reconstruction of the block on similar lines would cost about 2,200*l.*, but he considered it unwise, with the ever-increasing demand for office accommodation, that such an opportunity should be lost for increasing office space, and a scheme was submitted which would involve an expenditure of, roughly speaking, 4,000*l.* The matter was referred to a sub-committee.

THE CORROSION OF STEEL REINFORCEMENT IN CONCRETE.*

IT has been said that reinforced concrete should be avoided, as it is a treacherous material to use owing to the fact that the metal corrodes, and being covered by the concrete the extent of the corrosion can never be ascertained, and therefore many well-known engineers up to the present have avoided the use of the material owing to this impression. If they were right in their assumption, and the steel did corrode and there was no remedy for it, then reinforced concrete would soon have had its day, for its weakness in this respect would become generally known and it would naturally be avoided, but, from a series of experiments which the author has recently made and which he describes in this paper, he is in a position to state definitely that no such fears need be entertained. Before describing his own experiments he would in a few words set forth the gist of the information which we already have in relation to this important matter. In America the subject has received a good deal of consideration, and the commonly accepted theory in the United States respecting corrosion of iron in concrete is that stated by Professor S. B. Newbury, which is as follows:—

The rusting of iron consists in oxidation of the metal to the condition of hydrated oxide. It does not take place at ordinary temperatures in dry air, or in moist air free from carbonic oxide. The combined action of moisture and carbonic acid is necessary. Ferrous carbonate is first formed; this is at once oxidised to ferric oxide and the liberated carbon dioxide acts on a fresh portion of metal. Once started the corrosion proceeds rapidly, perhaps on account of galvanic action between the oxide and the metal. Water holding carbonic acid in solution, if free from oxygen, soon acts as an acid and rapidly attacks iron. In lime-water or soda solution the metal remains bright. The action of cement in preventing rust is now apparent. Portland cement contains about 63 per cent. lime. By the action of water it is converted into a crystalline mass of hydrated calcium silicate and calcium hydrate. In hardening it rapidly absorbs carbonic acid and becomes coated on the surface with a film of carbonate, cement mortar thus acting as an efficient protector of iron and preventing the carbonic acid molecules from attacking the metal. The action is therefore not due to the exclusion of the air, and even though the concrete be porous, and not in contact with the metal at all points, it will still filter out and neutralise the acid, and prevent its corrosive effect.

Some very important tests have been carried out by Professor C. L. Norton, of the Massachusetts Institute of Technology, Boston. These were conducted on the following lines. The blocks were made of (*a*) neat Portland cement, (*b*) one part cement and three parts sand, (*c*) one part cement and five parts broken stone, (*d*) one part cement and seven parts well-washed cinders.

The reinforcement of each block consisted of a ¼-inch rod, a piece of soft steel, 6 inches by 1 inch by $\frac{1}{16}$ inch, and a 6 inches by 1 inch piece of expanded metal. The tests were as follows:—One-fourth of the blocks were allowed to remain in air inside a building; one-fourth were placed in a sealed box in an atmosphere of air and steam; one-fourth in a sealed box in an atmosphere of air and carbon dioxide; one-fourth in a sealed box containing an atmosphere of steam, air and carbon dioxide.

Some of the reinforcement was dipped in cement grout previous to insertion in the concrete, but in other cases it was not.

The results of these experiments led Professor Norton to the following conclusions:—

1. That neat Portland cement, even in thin layers, is an effective preventative of rusting.

2. Concrete, to be effective in preventing rusting, must be dense and without voids and cracks. It should be mixed quite wet when applied to the metal.

3. The corrosion found in cinder concrete is mainly due to the iron oxide, or rust, in the cinders, and not to the sulphur.

4. Cinder concrete, if free from voids and well rammed when wet, is about as effective as stone concrete in protecting steel.

5. It is of the utmost importance that the steel be clean when bedded in concrete. Scraping, pickling, a sand-blast and lime should be used, if necessary, to have the metal clean when built into the wall.

These tests extended over a period only of three weeks, which, in the author's opinion, was not long enough.

For years past French engineers have protected many of their iron bridges by coating them with cement wash, two coats being usually applied, and in America cement wash has been largely used for a similar purpose.

M. Breuille, of France, states that from his experiments he came to the conclusion that in all cases the action of the cement in the concrete on the iron reinforcement prevented rust, and that it even removed the rust from iron which was already rusty when embedded in the concrete. The question of the rusting of steel in concrete has received the attention of German engineers and numerous tests have been made, the general conclusion arrived at being that cracks occurring in the concrete do not result in the reinforcement becoming corroded at these points. The method of testing was briefly as follows:—

Beams were prepared which were reinforced by the steel which is generally used in reinforced concrete structures, this steel being placed 1½ inch above the bottom of the beams. The concrete was mixed in the following proportions:—1 : 2 : 4, 10.1 per cent. of water being added. The forms were removed after a set of twenty-four hours; the beams were then stored for three months, some in wet sand, others in the open air, water being poured over them daily. For the next three months the beams were subjected to load tests, and of fifty-eight beams made twenty-six were broken under these tests. The thirty-two beams which had not been broken were then subjected to a rusting test under a load, sheet-iron casing being fixed around the middle third of the beam, through which a mixture of carbon dioxide, oxygen and water vapour passed. The beams were kept in this rusting atmosphere for three days from 7 A.M. to 4 P.M. The steel was then examined, with the following result:—

In twenty-seven out of the thirty-two cases no rusting had occurred. These twenty-seven beams had been subjected to a load causing stresses of 18,000 lb. to 35,000 lb. per square inch in the steel, and the five remaining beams had been subjected to a greater stress, viz. 35,000 lb. to 44,000 lb. per square inch.

Mr. J. M. Braxton, assistant engineer at Key West, Florida, U.S.A., recently reported to the engineer officer in charge of the fortification works on the East Coast of Florida that he had made fifteen sets of two blocks each, the aggregate in five of these sets consisting of three parts of coral sand, common to the beaches of the Florida coast, and five parts of brick crushed to pass through a 1-inch ring; in five others it consisted of three parts of coral sand to five parts of brick crushed to pass through a 2-inch ring; and in the remaining five blocks it consisted of three parts of silica sand and five parts of brick crushed to pass through a 1-inch ring. The blocks were 12 inches by 12 inches by 6 inches. The reinforcement, which in each case was inserted in the middle of the blocks, consisted of twisted steel rods, 8 inches long and ⅝ inch diameter. Some of the rods were dipped in grout, and others were not treated in any way. Half of these blocks were placed in the ocean after a twenty-four hours' set, and half were exposed to the air.

At the expiration of a period of one year and twenty-one days these blocks were broken, and it is interesting to note that the rods in those blocks which had remained in the sea water showed no signs of rusting, but those which had remained in air showed very slight rusting, regardless of the aggregate of which the blocks were made.

Some interesting tests were carried out a short time ago at the National Physical Laboratory, London, at the request of Sir John Brunner, and the following is the official report of these experiments:—

A strong wooden box was made and divided into five partitions, each partition being 12 inches long, 7½ inches wide, and 7½ inches deep. Specimens of mild steel of the following dimensions were prepared: (1) One inch diameter, 8 inches long, turned all over. (2) Eight-inch lengths cut from 1½ inch by 1½ inch bar with the scale left on. The partitions were half filled with good Portland cement concrete, and a specimen of each kind of steel laid on the top, the partitions being then completely filled with concrete. This was done on December 21, 1906. The blocks were covered with water several times per week for a year, and for three months afterwards they were left in the open, exposed to the weather. On April 20 one of the blocks was removed from the box and broken up, and the specimens removed. On examining the specimens carefully no trace of any action by the cement could be detected. The turned specimen was practically as bright as when it was put in, and the scale on the rough specimen was undisturbed. To test the possibility of any slight action, the surface of the turned specimen was polished and etched and examined under the microscope side by side with a specimen of the same material cut from the centre of the bar. No difference in the microstructure of the two specimens could be detected, and the conclusion is that in sixteen months no action has taken place between the metal and the concrete.

* A paper read on Monday, the 5th inst., by Ernest R. Matthews, A.M.Inst.C.E., F.R.S.E., before the Society of Engineers at the Royal United Service Institution.

Digitized by Google

While the preceding information is undoubtedly valuable it will be readily seen that the results of the investigations vary considerably.

Professor C. L. Norton found that corrosion took place when cinders were used as the aggregate of the blocks made by him; he also informs us that to dip the metal in cement grout was a sure proof against corrosion, but the metal must be clean before being dipped. This opinion is practically the same as that expressed by Professor S. B. Newbury.

M. Ereuille, of France, found that no corrosion took place when steel was inserted in concrete, but that the reverse occurred. He put rusty bars into concrete blocks, and when these blocks were broken some time after, they were found to be quite bright.

Mr. J. M. Braxton, on the other hand, found that slight rusting occurred when the blocks were placed in air, and that when submerged in sea water no corrosion of the metal occurred, while Sir John Brunner's tests indicate that no corrosion takes place when the blocks are placed in water and air alternately. In the German tests no corrosion occurred when reinforced beams were placed in air and others in wet sand, and afterwards subjected to a test load applied to produce a stress in the steel which did not exceed its elastic limit. The report of the special committee appointed by the Royal Institute of British Architects respecting this important matter should here be quoted. Their report, after dealing with other characteristics of reinforced concrete, goes on to say:—

It is sometimes thought that the metal may perish, but all experience shows that concrete is the best preservative for iron or steel known to us. A bar of iron or steel, slightly rusty, embedded in properly made concrete, may be taken out after some months, or after hundreds of years, brighter than when it was put in. Perhaps I may quote an instance (says Mr. W. J. Locke, Secretary R.I.B.A.); the experience of Mr. Somers Clarke, late Surveyor to St. Paul's Cathedral, who being anxious as to the condition of the great chain tie which binds the dome at its base, caused an opening to be made in the concrete in which it has been embedded for over two hundred years, and found the iron bright and perfect, notwithstanding the fears which had naturally been felt because of the percolation of water from the gallery over it. This is but one of many examples, showing not only that metal reinforcements and concrete have been used by architects for many years back, but that their confidence in the durability of concrete and metal in combination is justified.

The many instances of the anchor chains of suspension bridges being embedded in concrete as a provision against their deterioration through the action of moisture may also be cited as showing the reliance placed on concrete by engineers for the protection of steel from corrosion.

The author, about two and a half years ago, had occasion to pull down part of a concrete sea wall at Bridlington which had been built twenty-five years previously, and found that the iron chains which had been inserted in this wall at the time of its construction were still in a perfect condition, there being no sign of rust in spite of the fact that the sea covered the lower portion of the wall at every tide, and that in some places the chains were within an inch of the outside face of the wall.

The author will now describe the experiments recently made by him.

He set himself the task of discovering something definite on fourteen points, which are as follows:—

1. The effect upon the steel reinforcement of submerging blocks in 3 feet of fresh water, seven days after making them, and keeping the blocks in water for eleven weeks. (Steel untreated.)

2. The effect upon the steel of submerging blocks in 3 feet of fresh water after a forty-eight hours' set, and keeping the blocks in water for eleven weeks and five days. (Steel untreated.)

3. The effect upon the steel when the blocks are kept exposed to the air for twelve weeks. (Steel untreated.)

4. As No. 1, but when the steel is first dipped in cement grout.

5. As No. 2, but when the steel is first dipped in cement grout.

6. As No. 1, but when the steel is first dipped in linseed oil.

7. As No. 2, but when the steel is first dipped in linseed oil.

8. As No. 1, but when the steel is first dipped in turps.

9. As No. 2, but when the steel is first dipped in turps.

10. The effect upon the steel of keeping blocks, after a seven days' set, in water and air for alternate weeks for eleven weeks. (Steel untreated.)

11. The effect upon the steel of keeping blocks in water and air for alternate weeks for eleven weeks and five days after a forty-eight hours' set.

12. The effect upon rusty steel when the blocks are submerged in water for eleven weeks after a seven days' set.

13. The effect upon rusty steel when the block is submerged in water for eleven weeks and five days after a forty-eight hours' set.

14. As No. 13, but exposed to the air for twelve weeks.

The author had twenty concrete blocks made, formed of various aggregates, each being 8 inches cube. In some instances the aggregate consisted of:—Four parts broken bricks, two parts sand, one part Portland cement. In other instances the proportions were:—Three parts ¾-inch gauge slag, one part ⅛ inch and dust slag, one part sand, one part Portland cement; also:—Two parts ¾-inch gauge slag, one part ⅛ inch and dust slag, one part coke breeze, one part Portland cement; also:—Two parts broken stone, two parts ¾-inch slag, one part sand, one part Portland cement; also:—Three parts slag, two parts sand, one part Portland cement.

The analysis of the cement used was as given below:—

Chemical Analysis.

	Per cent.
Insoluble residue	0.82
Silica	20.43
Alumina	9.10
Oxide of iron	1.95
Lime	62.65
Magnesia	1.25
Sulphuric anhydride	1.38
Loss on ignition	1.66
Alkalies and loss	0.76
	100.00

The metal inserted also varied; in some cases it was put in in a rusty condition, in other cases it was clean. Some pieces of steel were dipped in cement grout, others in linseed oil, and others in turps.

The date when each block was made, the aggregate of which it was composed, the condition of the steel reinforcement when inserted, and the tests to which it was subjected, are clearly set out in the following table:—

Test Block in Reinforced Concrete.

Date when Block was made.	No. of Block.	Aggregate.	Steel.	Test to which the Blocks were subjected.
1908 July 20	1	4 parts broken brick 2 parts sand 1 part cement	1 piece rusty 1 piece clean —	Placed in water after 48 hours. — —
,,	2	Ditto	2 pieces rusty	Remained in the open air.
,,	3	Ditto	3 pieces rusty	Placed in sea-water 9 days after being made. Taken out of moulds 48 hours after making. This block was lost, so must not be included in these tests, as in the case with No. 8.
,,	4	3 parts ¾ in. gauge slag 1 part ⅛ in. and dust slag 1 part sand 1 part cement	3 pieces clean steel — — —	Kept in water after a 7 days' set. — — —
,,	5	Ditto	Ditto	Remained in the open air.
,,	6	Ditto	3 pieces dipped in linseed oil	Kept in water after a 7 days' set.
,,	7	Ditto	3 pieces dipped in turps	Ditto.
,,	8	Ditto	3 pieces clean	Placed in sea-water 9 days after being made. Taken out of moulds 48 hours after making.
,,	9	Ditto	Ditto	Placed in water 48 hours after making.
July 22	10	2 parts ¾ in. gauge slag 1 part ⅛ in. and dust slag 1 part coke breeze 1 part cement	— — 2 pieces dipped in linseed oil —	— — Remained in the open air. —
,,	11	Ditto	2 pieces dipped in turps	Ditto.

Block No. 1.—One piece of steel which was inserted in this block was rusty, it consisted of a short ¾-inch round bar. The block, after a forty-eight hours' test, remained in water until broken on October 13 (eleven weeks and five days). The author was surprised to find that this bar had improved considerably in appearance, and that where it was not actually pitted with oxidation, it had become quite bright, which was certainly not the case when placed within the block; he also found that the pitting had been considerably arrested.

The bright piece of steel which was inserted in this block was in precisely the same condition when taken out on October 13.

Block No. 2.—Two pieces of very badly corroded metal were inserted in this block; these consisted of ¾ inch and ⅝ inch round steel bars, and the block remained in air for twelve weeks. The author found that the steel had considerably improved, so much so that it was scarcely recognisable, most of the rust having disappeared.

Block No. 3.—This block was placed by the author upon the foreshore at Bridlington, but was so covered by the sand that it has not been found.

Block No. 4.—Three pieces of clean steel were inserted in this block, the latter being kept in water after a seven days' set, for eleven weeks. No rusting whatever occurred in these pieces of steel, notwithstanding the fact that the concrete was not particularly dense.

Block No. 5.—Three pieces of practically new steel (same as in No. 4 block) were here inserted, and the block remained in air for twelve weeks. The marks of corrosion which appear on the end of the round bar were there when the bar was inserted. The rusting, however, has considerably diminished, and it will be noticed upon close inspection of the bar that it is disappearing.

Block No. 6.—In this block three pieces of fairly clean steel, which had been previously dipped in linseed oil, were inserted. The block was placed in water seven days after making, and broken after it had remained in water for eleven weeks.

The author does not consider that this method of treating steel is a success, the coating of cement from the concrete being in his opinion a better preservative than oil. The slight marks of corrosion which occur on these bars were there when the steel was inserted.

Block No. 7.—Three pieces of clean steel previously dipped in turps were inserted in this block, the test being the same as in No. 6 block. The author's notes on this test are the same as in the previous case.

Block No. 8.—Placed on foreshore at Bridlington on July 29, 1908, found on November 24, 1908 (sixteen weeks and six days). *No corrosion.*

Block No. 9.—Three pieces of steel, slightly corroded, were inserted in this block, and the latter was placed in water after a forty-eight hours' set, and kept in water for eleven weeks and five days. In one of these pieces of steel new corrosion is visible; this, in the author's opinion, is accounted for by the fact that the piece of steel referred to was very near the surface of the block, and it will be also noted from the foregoing table that the aggregate in this block consists chiefly of small slag, which in the author's opinion is most unsuitable for concrete that is to be in contact with water.

Block No. 10.—In this block two pieces of fairly clean steel were inserted, which had been dipped in linseed oil; the rusting on these bars is very pronounced. This block remained in air for eleven weeks and five days after making; the concrete contained one part coke breeze, but was very dense and of excellent hardness.

The author feels convinced that the linseed oil coating accounted partly for the corrosion, preventing the cement from coming in contact with the steel, and he also considers that coke breeze is not a suitable material to use in concrete which has to come in contact with exposed air.

Block No. 11.—The aggregate was the same in this block, the steel being dipped in turps. The corrosion is very bad, and in the author's opinion is due to a large extent to the coating, as was the case with No. 10. This block was in air for eleven weeks and five days. The concrete was dense and good, although it contained one part of coke breeze.

Block No. 12.—In this block the aggregate was precisely the same as in Blocks 10 and 11, but the steel was clean and not coated in any way. The block was kept in air and water for alternate weeks for twelve weeks, and the steel was found to be in a perfect condition. The edges of the steel were filed before insertion, and were quite bright both before and after testing.

Block No. 13.—The aggregate in this block was the same as in the previous three, the steel bars were dipped in cement grout, and the blocks were kept in water after a seven days' set for eleven weeks. The steel was in an equally good condition when taken out as when inserted, in spite of the fact that the concrete contained one part of coke breeze.

Block No. 14.—Two pieces of rusty steel were inserted in this block, the aggregate being the same as in the previous four blocks. The block was placed in water after a seven days' set and kept in water for eleven weeks. The steel was not coated in any way, and it came out with the rust almost gone. The steel was quite wet when taken out, on account of the porous nature of the concrete.

Block No. 15.—This is practically the same test as in Block No. 14, three pieces of rusty steel were inserted in this case, and the same result obtained.

Block No. 16.—The aggregate in this case was more suitable, consisting of two parts broken stone, two parts ¾ inch slag, one part sand and one part cement. Two pieces of clean steel were inserted. The block was kept in air for twelve weeks. The steel was in perfect condition when taken out, there being no signs of rust.

Block No. 17.—Two pieces of clean steel were inserted in this block, the aggregate and tests being the same as in No. 16, the result also being the same.

Block No. 18.—Three pieces of rusty steel were inserted in this case, the aggregate and tests being the same as in Nos. 16 and 17. The steel was very badly corroded before insertion, but when taken out much of the rust had disappeared, which leaves no doubt in the author's mind as to the preserving properties of cement.

Block No. 19.—Two pieces of clean steel, previously dipped in cement grout, were inserted in this block, the aggregate being the same as in No. 20. The block, after a seven days' set, was kept for alternate weeks in water and air for eleven weeks. Slight indications of rusting occurred, which the author attributes to two causes:—(1) That the concrete was not sufficiently dense. In blocks Nos. 19 and 20 river sand was used, which in the author's opinion is not so suitable for dense concrete as crushed sand or sharp land sand. (2) That where the slight rusting occurred the cement grout appears to have been rubbed off, the bare metal being visible. This might occur in handling these bars if the grout had not properly dried on to the bar.

Block No. 20.—The aggregate in this case consisted of three parts slag, two of sand and one of cement. Two pieces of clean steel were inserted, each being previously dipped in cement grout. These blocks were placed in water after a seven days' set and kept in water for eleven weeks. The edges of the steel bars were filed bright before the bars were inserted. No corrosion occurred, the edges being just as bright when the steel was taken out of the blocks as when it was inserted.

Test No. 21.—This is a somewhat interesting test. A reinforced concrete lintel made by the Chain Concrete Syndicate, of Leeds, ten months ago, became broken in moving and had to be replaced. It has remained in the open yard of the above company ever since. It was broken for the author on October 13, 1908, and the two steel clips, which projected out of the concrete for about 2 inches, were taken out, and the author found that the rust occurred exactly on the line of the concrete face. The preservation of the portion of steel in the concrete was perfect, no rust whatever having occurred, although the lintel has been out in all states of the weather.

Notes in General.—No absolutely bright steel was used by

Digitized by Google

the author in these experiments; what is called "new" steel refers to the dark mill colour, a sort of blue.

Again, the concrete used in these blocks was in no way specially prepared; in fact, in some cases it was rather carelessly done, with a purpose—namely, to make the test more severe.

Conclusions arrived at.—The results of the foregoing experiments have led the author to the following conclusions:—

1. That rusty steel embedded in concrete will in a very short time become bright, regardless of whether the concrete is in water or air. This point has, in the author's opinion, been conclusively proved by his experiments.

2. That the application of cement grout to steel is an effectual safeguard against corrosion, but that the greatest care should be taken in the grouting process to see that every portion of the steel is well coated, and that before the steel is embedded in the concrete the cement grout is allowed to become quite dry upon the steel.

3. That if the aggregate used for the concrete is not porous and the concrete is well mixed, the reinforcement being well embedded, no cement coating is needed. This is proved by test No. 21. (Seeing that the application of a coat of cement grout is such an inexpensive procedure, the author makes it a rule in carrying out work of this kind to have all reinforcement coated in this manner.)

4. That no porous materials, such as coke breeze or slag, should be used in connection with reinforced concrete work, if such concrete is intended to be under water or exposed to the air.

5. That linseed oil or turps, or probably any other coating except cement or lime, applied to steel before its insertion in concrete, facilitates rather than prevents the rusting of the metal.

6. That it is of great importance to see that the reinforcing steel is well embedded in the concrete, so that every portion of it is covered with cement.

7. That the best results were obtained when the aggregate consisted chiefly of broken stone or brickbats. Gravel would no doubt answer as well.

The author was surprised that such a good result was obtained with an aggregate composed of brickbats.

8. That river sand, generally speaking, is not satisfactory for reinforced concrete work where such work is required to be watertight.

The author ventures to think that the conclusions which he has arrived at are of great importance, and should ease the minds of those engineers who up to the present time have had considerable doubt regarding this matter; he also hopes that the attention of the Local Government Board will be drawn to these experiments and the conclusions arrived at, and that this will result in the period for repayment of loans for work of this class being considerably extended.

He would express his indebtedness to the Chain Concrete Syndicate, of Leeds, for allowing the tests to be carried out at their works, and more particularly to Mr. A. Mitchell, one of the partners in that firm, for the valuable assistance which he rendered to the author in the carrying out of these tests.

The PRESIDENT proposed a vote of thanks to the author of the paper. The subject of reinforced concrete, he said, was very much to the fore at the present time, and all who engaged in constructive work were interested in it. The attitude taken up by the Government departments, particularly the Local Government Board, and to which the paper referred, had to a certain extent hindered the use of reinforced concrete in carrying out public works for municipal undertakings, but in spite of that hindrance, which he ventured to think was well founded, the use of reinforced concrete was continually extending, and therefore it was highly important that they should have definite facts brought before them in regard to the behaviour of the materials of which it was composed. He thought they would all agree with Mr. Matthews that it was dangerous to use any but the finest materials for aggregates, and the President said he would hesitate about using slag or cinders, because they knew that those materials had a highly corrosive effect. The coating of bars before they were inserted into concrete had been alluded to in the paper, and the author suggested that such treatment might be a source of weakness. The point, he hoped, would be referred to in the discussion, because a coating of cement was a very efficient way of protecting steel from salt water.

Mr. C. F. MARSH said that the most interesting and instructive experiments mentioned in the paper were those carried out by the German engineers, because the beams were tested by loads to produce a stress equal almost to the elastic limit, and yet there were no signs of corrosion. He suggested that another interesting test which could be carried out under conditions similar to the other by Mr. Matthews would be to make a beam of reinforced concrete and subject it to loading until the first visible crack appeared, then to leave the beam under the load between high and low tide, so that the beam would be alternately wet and dry. The coating of steel with linseed oil would destroy cohesion and the practice was not a good one. The tests of Blocks 14 and 18 were very interesting in showing how rust disappeared from steel when it was embedded in properly made concrete. He had noticed the same thing himself that rust on steel did disappear, and in specifications he always permitted the steel to be rusty so long as there was no loose rust when the metal was embedded. There was no doubt that the main thing to preserve steel was to embed it in carefully and properly made concrete, put in in a proper manner and not too dry. In cases of rusting he thought they would find that the concrete when used had been too dry a mixture.

Mr. H. D. SEARLES-WOOD said it was a very good thing to collect together facts concerning concrete experiments, and in the concise form of the lecturer's paper his information formed a valuable reference. There was a great deal of doubt about rusting in the reinforcement of steelwork, and he thought it was probably due to the failure of expanded metal when it was used instead of laths for plaster ceilings. He presumed that the reason for failure in that case was because the metal was only partially covered, and he thought where expanded metal was used as reinforced concrete it might be liable under certain conditions to follow in the same way.

Mr. BERTRAM BLOUNT, F.I.C., said it seemed from the paper that engineers had begun to understand that the changes under different conditions of the materials which they had to use came under the purview of the chemist. Thus it was that chemical protection by alkaline treatment would suffice to arrest corrosion in crevices and gaps in properly constructed reinforced concrete. He agreed with the author that if an aggregate in itself was unduly porous there might be trouble, porous in the sense that it let liquid through and porous in the sense that it gets the cement away from the material, the core of steel, and consequently it followed, as had been proved in reinforced construction, that the concrete must be particularly good and particularly dense and thoroughly in contact with the metallic core used in the reinforcement. He believed that if those simple principles were observed and if the underlying fact was kept in view—i.e. that clean iron was not likely to suffer oxidation under an alkaline medium—all doubts as to reinforced construction would disappear.

Professor H. ADAMS regretted that the experiments quoted by the author were comparatively small in number, and more particularly that so short a time was allowed for the tests. Eleven weeks was almost a microscopical time for convincing results. He questioned, too, the accuracy of some of the chemical descriptions, more especially those accredited to Professor Newbury and Professor C. L. Norton. With regard to the painting of the bars with grout, the speaker said he always had held the opinion that the grout should not be allowed to dry too much before insertion. Iron chains were the most extravagant method of reinforcement, because the metal must necessarily double upon itself; straight bars were economical.

Mr. H. ELLIS HILL, M.I.C.E., assumed that ferro-concrete should be made more or less like other good concretes. With regard to the coating of the steel bars with cement wash, the practice was long established and well known to all engineers who had to do with shipbuilding.

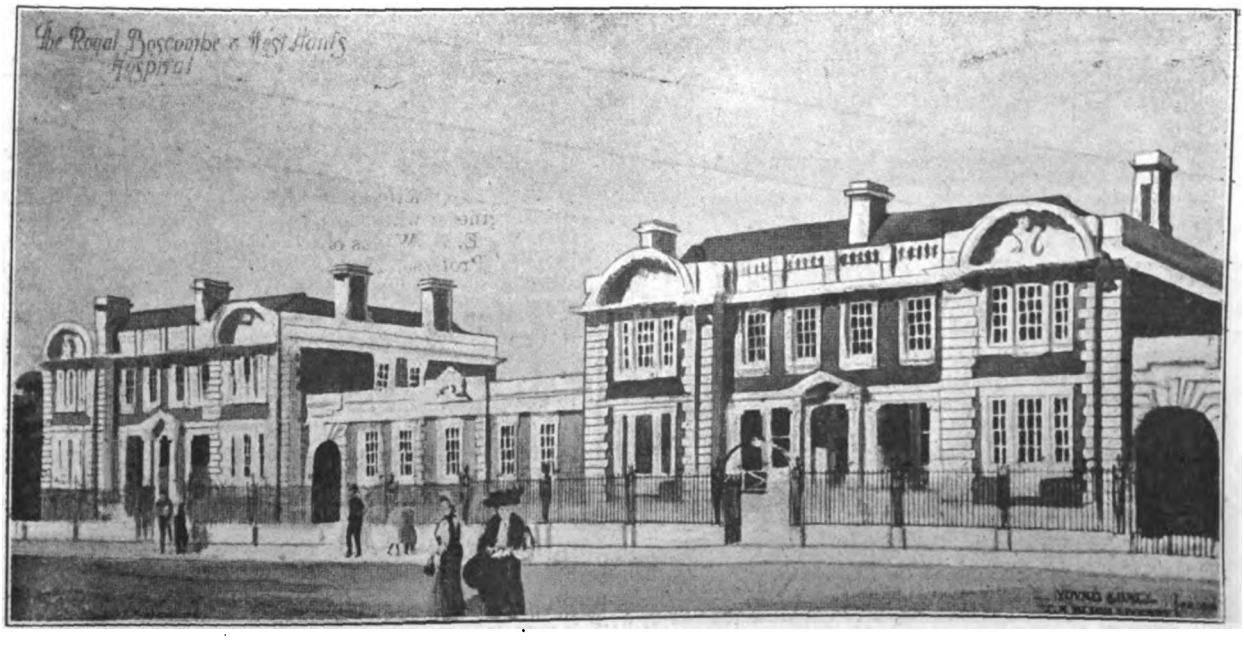
Mr. E. P. WELLS observed that if the experiments carried out by Professor Norton had been for a period of three years different conclusions would have been arrived at. He was of opinion that cement grout should not be put in close contact with a metal to be used in reinforced construction. The speaker disapproved of the use of clinker and cinder in aggregates. He thought that if Mr. Matthews would continue his experiments for twelve months as an absolute minimum, and experiment largely with concrete and with different aggregates all made at the same time and of the same cement, that the results of his tests would be more positive. He quite agreed with the remarks about coating steel rods with turps or boiled oil. With regard to river sand, he had always found it perfectly satisfactory. Its quality depended upon where it came from, and when sharp and clean he had, he said, no hesitation at all in using it, for where the concrete was properly made he had never found percolation.

Digitized by Google

Mr. D. B. BUTLER said it seemed to him that, after all, if concrete was well made and not too porous, the reinforcement would be found perfectly good after any length of time. He endorsed, however, Mr. Wells's opinion that eleven weeks was a very short period in which to test materials for reliable data. With regard to the use of coke breeze, slag or coal residue, as it was called in Germany, he believed the Government of that country had forbidden its use in the making of aggregates, for extensive tests of the material had proved it to be unsatisfactory with concrete. The speaker agreed with others that a cement grout coating to a beam, when allowed to dry, prevented cohesion between metal and cement. The better way was to insert the beam in a wet state into the concrete or see that the concrete was thoroughly in contact with the reinforcement. In a case of failure of concrete piles which came under his notice he found that the piles had splintered and split, and on examination it was seen that not more than 20 per cent. of the area of reinforcement was in contact with the concrete, and therefore the whole object of the reinforcement was nullified and hence the failure. Of course, the coating of reinforced beams with oil and turps was several degrees worse than coating with cement grouting.

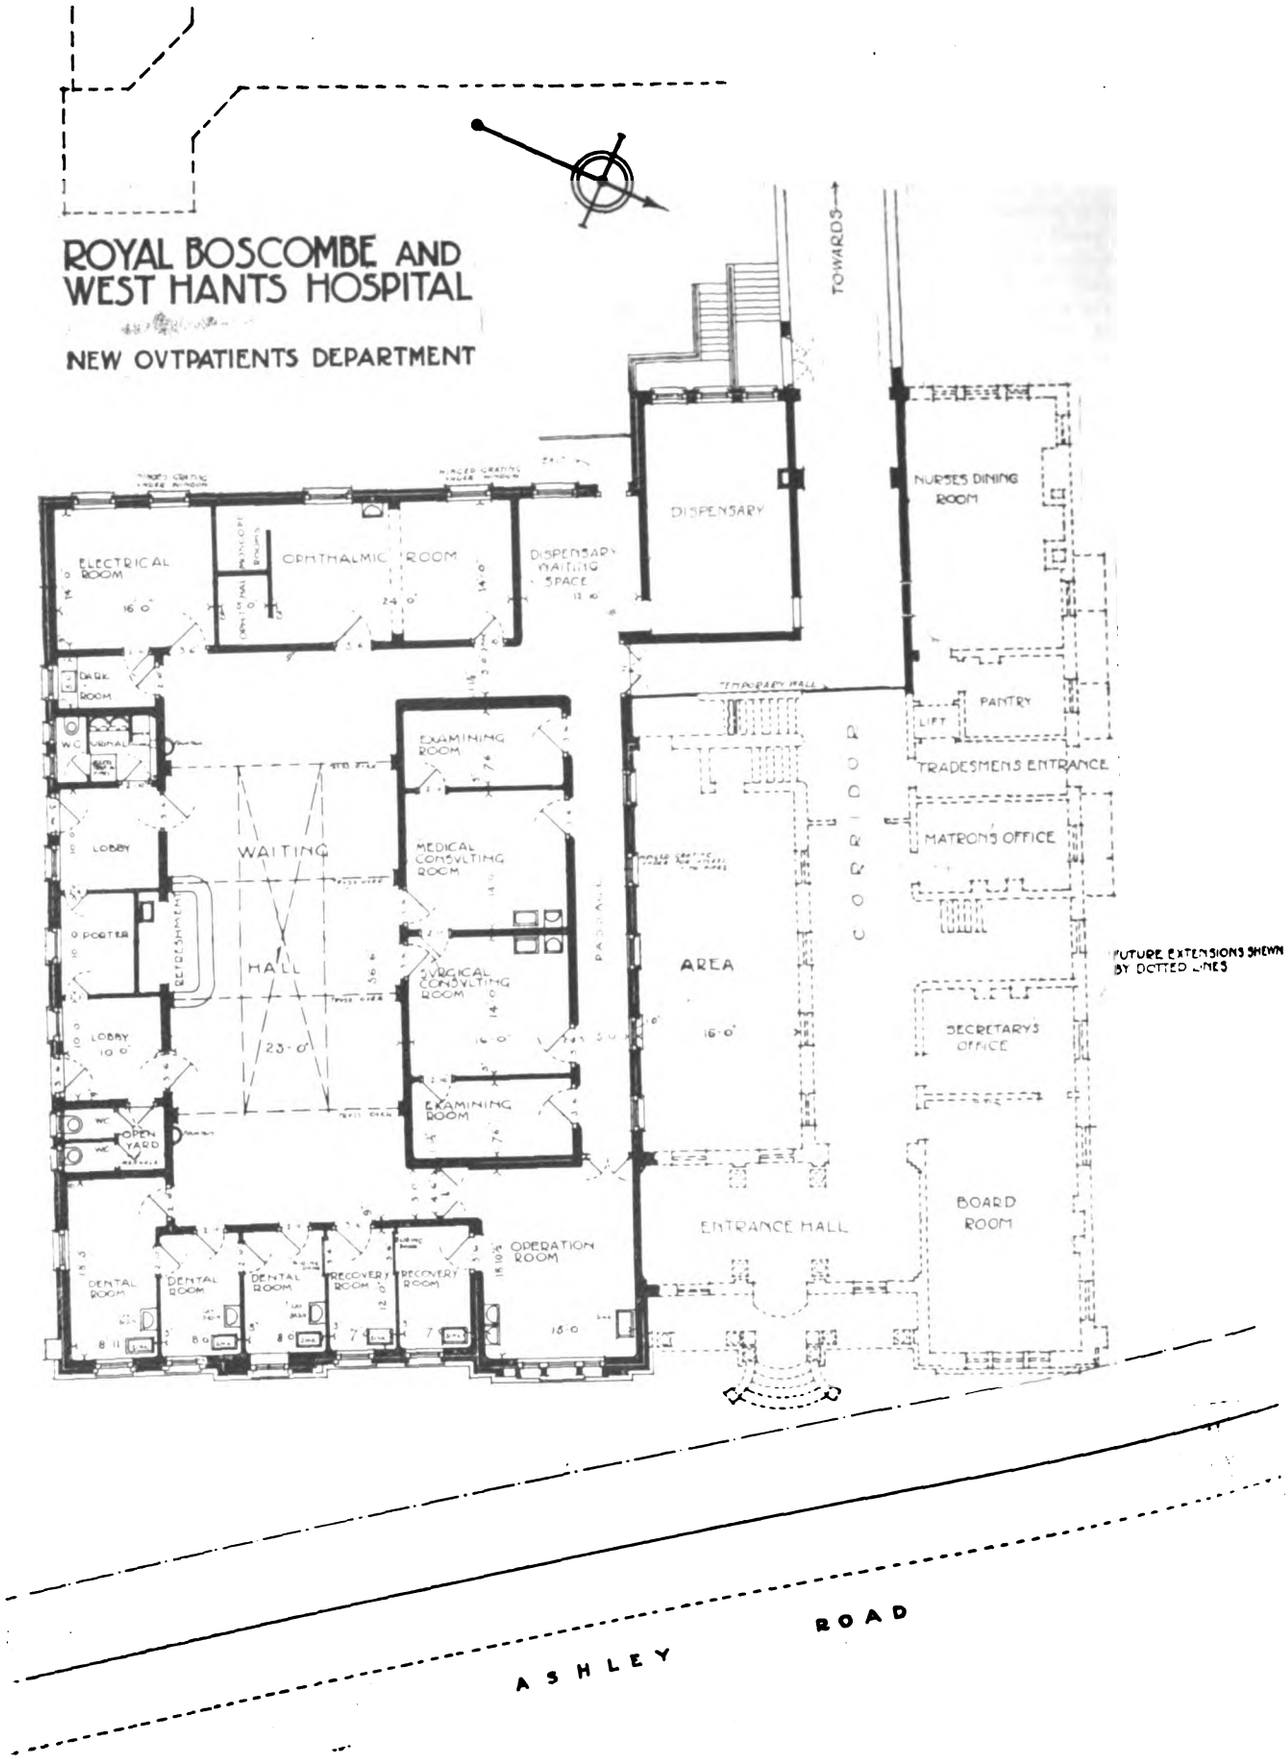
Mr. MATT. GARBUTT thought the tests undertaken by the author were interesting and useful, but as their buildings must necessarily last out the building lease, they ought to endeavour to ascertain what would happen to reinforced construction after a long term of years. It appeared to him that the element of time and the amount of cover protecting the metal were extremely important factors. The periods of the tests were unfortunately short, nor had the author indicated how much cover his material received. There were, of course, instances known to them where reinforced material had withstood the test of years—the chain in the dome of St. Paul's was a familiar example—but the metal in that instance was embedded some feet. The metal in the sea wall to which the author had referred was also probably deeply embedded. He thought it would be well to ascertain how reinforced metal thinly covered was affected. He had had an opportunity of examining some embedded iron rods which had served on the edge of a swimming-bath for twenty years. The concrete was of very good quality, and some of the rods on extraction were found to be quite without rust; other rods showed distinct rust, due to cracks in the reinforcement, though the apertures were so fine that they could not be detected so long as the rods were not subjected to tensile stress. The question of small cracks under tension was interesting, and though many contended it was not important, it seemed to him that however fine the crack, given sufficient time the reinforced metal would rust.

Mr. R. W. VAWDREY quoted from a paper of the International Navigation Congress held in Russia, in which the permanence of reinforced concrete was fully discussed. At that Congress Mr. W. B. Douglas reported that in the construction of the first Eddystone Lighthouse, which he took down in 1884, a bundle of rods accidentally left in the concrete was found. They were in perfect condition, the lime concrete having withstood exposure to the action of sea water during 150 years or thereabouts. Mr. Colson, another witness at the Congress, had mentioned the instance of a wall about 200 years old, in demolishing which nails in perfectly good condition were found. In both cases the depth of covering would be considerable, which differentiated the two cases from those of a covering of an inch or so. It appeared to be generally agreed by the engineers at the Congress that cement concrete in sea water was liable to serious deterioration, but by the addition of a material such as trass or other volcanic substances that deterioration would be stopped.



Mr. B. J. BELCHER suggested that "new" steel should be allowed to rust in order to remove the mill "blue," the rust afterwards being cleaned off by wire brushing.

Messrs. T. J. FENWICK, F. J. BACON, A. B. JOSCELYNE, A. S. E. ACKERMANN and Dr. J. S. OWENS supported the vote of thanks to the lecturer, who briefly replied. He contended that in tests extending to eleven weeks some signs of rusting would have occurred; the results, therefore, of his experiments were sufficient to enable them to come to definite conclusions.



THE ROYAL BOSCOMBE AND WEST HANTS HOSPITAL.

THE building, which was opened by H.R.H. Princess Alexander of Teck on April 3, comprises the whole of a new out-patient department and is part of a larger scheme which, when completed, will contain the hospital administrative offices and accommodation for resident medical officers and nursing staff.

The out-patient department is entirely on the ground floor, and is entered from a side road leading out of the Ashley Road. Two separate entrances are provided, one for male and the other for female out-patients, and between the two is the porter's lodge. The entrance door in each case gives access into a square lobby, and from thence the patients pass into a large waiting hall, 56 feet long by 23 feet wide. Leading out of each of the entrance lobbies are lavatory arrangements for patients. Consulting-rooms are arranged on three sides of the hall; on the north the medical and surgical consulting-rooms, each with its own examining-room, will be found. On the east is the minor operation-room, with two recovery-rooms, and the dental department, which consists of three rooms. On the west is the electrical department and the ophthalmic consulting-room, with two dark-rooms. From the consulting-rooms the patients pass by a separate passage to a small waiting-room adjoining the dispensary, where they are served with their medicine, and from here they pass out to a path returning to the street. The patients thus follow a definite course, and do not retrace their footsteps or cross other patients at any point. On the

Digitized by Google

Digitized by Google

south side of the hall is a refreshment-bar. The out-patient department is connected by a light and airy main corridor with the ward blocks.

The building which yet remains to complete the block will contain the main entrance to the hospital, board-room, secretary's office, matron's office, tradesmen's entrance, pantry, nurses' dining-room—all on the ground floor. On the upper floor the rooms for the resident medical officers, the servants' hall, pantry and kitchen will be found. The buildings as illustrated show the out-patient department in the centre, with the future administration block and the nurses' home on either side, forming a well-balanced façade to the Ashley Road. The architectural style adopted is a somewhat free treatment of the Georgian, adapted to modern requirements, and is carried out in red facing rubbed brick and Portland stone. Generally, the walls are faced with Bridgwater brick, and finished internally with Keene's cement and Hall's sanitary paint over a dado of green glazed brick with white glazed fillings. All angles are rounded, and the fireproof floors are finished with marble terrazzo throughout. The sanitary appliances and fittings are of the most modern and up-to-date pattern and design, supplied by Messrs. Dent & Hellyer, London. The contractors for the building are Messrs. Miller & Son, of Bournemouth. The fireproof floors were laid by Messrs. Mark Fawcett & Co., Messrs. Diespeker were responsible for the marble mosaic, and the hot-water engineering has been carried out by Messrs. Henry Hope & Son, of Birmingham, while the electric lighting and power installation is by Messrs. Henry Fellowes & Co., of Westbourne, Bournemouth. The new buildings have been designed and carried out under the superintendence of Messrs. Young & Hall, F.R.I.B.A., of London, and Mr. G. A. Bligh Livesay, F.R.I.B.A., of Bournemouth, joint architects.

THE SOCIETY OF ORDAINED SURVEYORS

THE Council of the above Society, at the annual meeting on Monday in the rooms, 117 George Street, Edinburgh, submitted its tenth annual report on the work of the past session.

The adjustments of the draft modes of measurement for minor trades have been completed by the sub-committee, and will be submitted to the members for approval at an early special general meeting.

The Council would strongly impress upon members the necessity of complying with the regulations relating to the completion and registration of indentures.

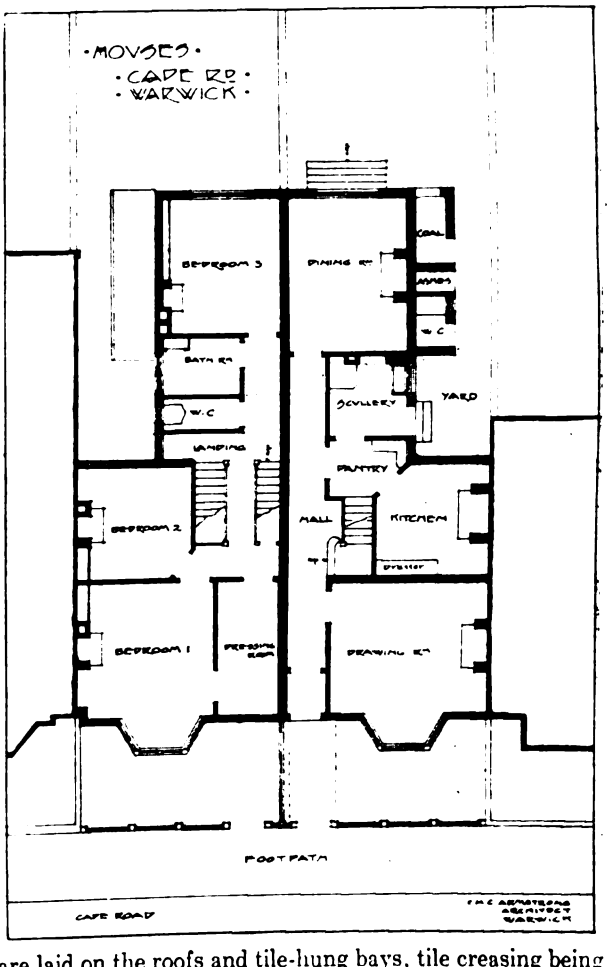
The treasurer's balance-sheet for the year shows the funds of the Society at the close of the financial year amounted to 504*l.* 13*s.* 5*d.*

The General Examining Board met on four occasions during the past session.

Preliminary Examination.—There were as usual two diets of examination held during the year, in April and October. Seven candidates in all were examined, of whom two were for re-examination. Of the seven examined, one passed in one subject and is through the examination, two passed in three subjects and are through the examination, two passed in one subject and failed in two subjects, and two failed in two subjects.

Final Examination.—Two diets of examination were held during the session. Two candidates came forward at the April diet, one for examination and one for re-examination in the first division. The former succeeded in passing. There were no candidates in the second division. At the October diet one candidate came forward for examination in the second division, but was not successful.

Diets of Examination.—In accordance with the rules of the Society the diets for examinations are fixed by the Board. Hitherto two diets have been held in each year for each examination—namely, in April and October. The Board are of opinion that one diet of examination, to be held in April yearly, would in future be sufficient, but before making a change in this direction they would prefer to have an expression of opinion from the members of the Society at the annual meeting.



Indentures.—During the year four indentures and two discharges of indentures were registered.

Professor Henry Adams, M.I.C.E., will read a paper on the 14th inst. on "Stresses and Strains in Girder Work," illustrated by indiarubber model and lantern slides, before the Association of Engineers-in-Charge at St. Bride's Institute, E.C.

HOUSES, CAPE ROAD, WARWICK.

THESE two houses have recently been erected in the Cape Road at Warwick, filling an open site between existing buildings, each house having a frontage of 20 feet. Sand-faced 2¼ inch bricks with a wide joint are used on the front elevations and chimney-stacks. Brindled tiles

are laid on the roofs and tile-hung bays, tile creasing being introduced on the stacks and party wall, the latter having a brick on edge coping. The windows are casements with wide wooden bars, and the whole of the woodwork is

Digitized by Google

painted white, with the exception of the doors, which are dark green. Each house has two good attic bedrooms in the front roof, and cellaring is provided under the kitchens. The front hall and passage is paved with small red tiles, the scullery and pantry being blue-brick paved. The range and grates were supplied by Messrs. JOHN WARD & CROFT, of Birmingham. Electric bells and town gas are installed throughout. The front fencing and gates are carried out in oak to special details on a brick base. The gardens run back 40 feet, the drainage being taken into a main sewer in the road here. Mr. C. M. C. ARMSTRONG, of Warwick, was the architect, Messrs. T. BAILEY & Co., of Clarendon Avenue, Leamington, carrying out the work under his supervision.

Correspondence

[The Editor will not be responsible for the opinions expressed by Correspondents.]

The Beauty of Bath.

SIR,—In support of the preservation of architectural remains of interest, the late Mr. Street, R.A., whose opinion on such matters was always respected, said in his address (1881) before the Royal Institute of Architects:—"I hope we are all agreed that there is no work in which we can do better service to our art than by sturdily opposing all schemes for the destruction of existing works of architectural art or constructions of historical interest."

A writer in the *Contemporary Review*, July 1884, says:—"The beauty that has been thought beautiful for 200 years is worth examining, for in matters of art time is the final judge. Fashions come and go; to have outlived many fashions, yet always to have been thought admirable, is the highest distinction human nature can obtain." Surely Bath and its architectural beauty belongs not only to England, but to the travelled stranger who visits it from afar and sees in the graceful buildings a beauty that has escaped our own countrymen. It is the duty of citizens to guard the rich possessions they inherit. Other cities, as Stratford-on-Avon, Chester, Norwich, have their own special features, and certainly Bath can be included in the list. The recent meeting on March 27 and the opinions of cultured experts on the preservation of the buildings in Bath Street should act as a deterrent to further destruction. Is it too late to protest?

Public opinion will be against such contemplated spoliation, and I am glad a society has been formed, with the Rector of Bath as President, to ensure proper oversight of this beautiful city.—Yours, &c.,

London: March 31, 1909. S. W. KERSHAW.

Ingress Hall, Kent.

SIR,—Could you or any of your readers kindly inform me whom Alderman Harmer employed as architect to design Ingress Hall, sometimes erroneously called "Ir gress Abbey" (as it never was one), near Greenhithe, in Kent? It was erected in 1833 by Alderman James Harmer from the stones of old London Bridge, and its appearance from the River Thames is very picturesque. It almost looks like the work of Welby Pugin, but perhaps some of your readers can tell me. I heard lately that it was going to be turned into a manufactory, but I hope this is not so.—Yours very truly,

W. F. POTTER.

18 York Grove, Queen's Road, S.E.

GENERAL.

A Figure of Aristotle, by Mr. G. Walker, sculptor, has recently been placed in the niche prepared for it outside the south wall of the Gladstone Memorial Library, Hawarden. It is the gift of the Dean of Lincoln and Mrs. Wickham. The four niches outside St. Deiniol's are intended for the figures of those four great men who were regarded by Mr. Gladstone as his chief masters, viz., Aristotle, St. Augustine, Dante and Bishop Butler. Three are now in position, all of them the work of Mr. Walker. It only remains for that of Bishop Butler to be given to complete the set.

At a Meeting of the general committee of the Liverpool Cathedral held on Monday it was announced that Miss Langton and Mrs. H. B. Gilmour are jointly contributing a sum of money sufficient to provide marble flooring for the Lady chapel. The floor will be laid in squares of green and white marble.

Sir Aston Webb, R.A., has been instructed by the Governors of the Imperial College of Science and Technology to prepare the necessary plans and to obtain tenders for the new building for mining, metallurgy and geology to be erected in Prince Consort Road, and also to prepare plans for the extension of the engineering departments of the City and Guilds of London College in Exhibition Road and Prince Consort Road. The erection of the new mining building is expected to begin almost at once, and steps are being taken in connection with the foundation-stone ceremonial.

The Winchester Town Council have accepted an offer from the Dean and Chapter of Winchester Cathedral to present to the city a stone screen designed and erected in the reign of Charles I. at the entrance to the choir of the cathedral by Inigo Jones. This screen was removed in 1820 to make way for a stone Gothic screen. Inigo Jones's work was stored in the triforium of the south transept, from which it was recently removed owing to its great weight, which added danger to that part of the building. The Council will shortly proceed to consider its re-erection on public property.

The Trustees of the Victoria Memorial, Calcutta, have referred the question of the erection of the hall to a local committee comprising seven citizens of Calcutta, with Mr. Graham, Chairman of the Calcutta Chamber of Commerce, as President. All papers, including the opinions lately expressed by Sir William Emerson, will be placed at the disposal of the committee, who will be asked to pronounce a final verdict.

Provision has been made in the current year's estimates which will enable the directors and trustees of the National Portrait Gallery to open that institution on Sundays throughout the year, as is now done in the case of the National and Tate Galleries.

The Upper Norwood Athenæum will hold its next meeting on April 17 at the Roman Bath, in the Strand, W.C.; a visit will also be paid to the Savoy Chapel, to the R.C. Sardinian Chapel, and the church of St. Clement Danes. A tea will afterwards take place at Anderton's Hotel, Fleet Street, after which a paper will be read on the places visited by Mr. Jonathan Downes, its former hon. secretary. Among the ancient monarchs who are supposed to have visited St. Clement Danes are King Canute and his two sons and successors.

The York City Council on Monday agreed to make application for a loan of 25,000*l.* for the purchase of property necessary for the formation and completion of the new streets from the Pavement to Piccadilly.

The Local Government Board, having considered the report of their inspector on the recent inquiry held by him as to the proposal of the Paddington Borough Council to sell the Queen's Road baths to Messrs. Whiteley, Ltd., for 60,000*l.* and erect baths elsewhere with the proceeds, decline to sanction the arrangement. While the Board do not oppose the sale of the property, they are not satisfied that 60,000*l.* is the highest price that can be obtained, and they suggest a revaluation by a valuer to be named by them.

The First Commissioner of Works was asked on Monday in the House of Commons whether it was his intention to consider schemes for the improvement of the Horse Guards Parade and its surroundings; and, if so, whether the work would be commenced during next autumn. Mr. Harcourt, M.P., in reply, said none of the schemes which have been submitted to him for the so-called improvement of the Horse Guards Parade have commended themselves to him, so therefore he is not proposing to commence any work there during the autumn.

The Finance Committee of the Manchester Corporation state that they raise no objection to the proposed application for borrowing powers for a loan of 20,000*l.* for baths to be erected at Withington. The site is in Burton Road, opposite the Waterloo Hotel. The land surrounding the site is vacant, and it is intended to lay out a new street on the north side. A short flight of steps leads up to the men's second-class swimming-bath, which is 75 feet by 21 feet and has sixty dressing-boxes; and the men's first-class swimming-bath, which is 75 feet by 25 feet and has forty-six dressing-boxes. The women's swimming-bath is 75 feet by 21 feet.

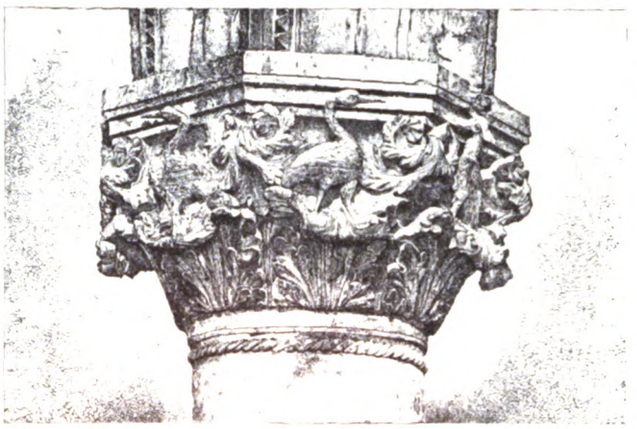
SCULPTURED PANELS BY DONATELLO.



THE WEEK.

We have been favoured with a copy of the correspondence between Mr. F. W. Speaight and the Right Hon. Lewis Harcourt, M.P., His Majesty's First Commissioner of Works, with reference to the former's suggestion for the improvement of the Horse Guards Parade and the alteration of St. James's Park. The essence of the correspondence is that the First Commissioner has "no intention of doing anything to destroy the historic associations or the present beauties of one of the most charming of the London parks," and that as he believes Mr. Speaight's scheme of alterations would have this effect, he is "unable to promise them any favourable consideration." We quite agree with the First Commissioner's opinion, whilst we recognise that Mr. Speaight's proposal would give us an example of park planning in the grand manner of which we have too few examples in England. Mr. Harcourt has had, therefore, to choose between the maintenance of "one of the most charming of London parks" of a particularly English type, and a piece of formal vista planning, excellent of its kind, but of more Continental fashion. It is purely a matter of personal taste as to whether the informal laying out of St. James's Park, as it at present exists, or the formal arrangement proposed by Mr. Speaight is preferable; neither, on any ground, is better, and the First Commissioner is, in our opinion, quite justified in maintaining the *status quo*, and will have the approval of very many Londoners in so doing.

Although we are quite in accord with the protest of the Manchester Society of Architects, recorded in the letter we publish in our correspondence column, this does not prevent us from congratulating Mr. Whitmore, the county architect for Essex, on the failure of the attempt to deprive him of the privilege he has hitherto enjoyed of acting as architect for new county schools on "payment of commission or honorarium therefor." There is all the difference in the world between the position of a county architect or surveyor of the old *régime*, who was generally a professional man in private practice retained at an annual fee for certain regular routine work of inspection, and the more modern type of salaried official, with office and assistants provided and paid for by the County Council or other public authority. The former was remunerated for particular services as architect by a commission or honorarium, this being virtually an agreed fee for specified work. The latter gets his salary, whether his work be large or small. When there is an increase of work, there is an increase of staff which does not always diminish when the urgent need for their services ceases. Added to this is the well-known fact to those who are acquainted with the realities of officialdom, that amongst salaried professional employés, as amongst artisans, less work, and considerably less, is done by those paid by time than by those paid by the piece. We are certain, from an intimate knowledge of the ways of public servants, that the main point put forward by the Manchester Society of Architects is absolutely true, that the ratepayers spend far more for professional services by salaried officials than they would do for those by architects, engineers, or surveyors in private and independent practice. The salary list is not the only cost, as is usually assumed by defenders of the official system. Rent, stationery and office expenses of every kind ought to be, but generally are not, included, and, above all, it is ignored that any given building will nearly always cost more to erect if designed and superintended by salaried officials rather than by private practitioners.

Architects do not always realise their responsibility for the carrying out of the drawings and specifications prepared by them and forming the basis of the contract between their clients and the builders. Messrs. Gough, Trollope & Co. have recently had an unpleasant experience which they have faced in a highly creditable and honourable manner. They were the architects, selected in open competition a few years ago, for a new workhouse infirmary at Leicester, which was erected under their superintendence at a cost of about 120,000*l*. Recently dry rot or other fungoid growths appeared in the ground floor, and Mr. Alderman Sawday, a local architect, being called in to investigate the cause, reported that he found that 5,000 wooden stakes had been placed in the concrete under the floors, and that the fungoid growths proceeded from these. It is quite clear what had happened; the stakes were used by the concretors for working the levels of the concrete and left in. The architects might have thrown the blame on the clerk of works or builders' foreman, but they, wisely perhaps in the present view that lawyers take of an architect's duties, accepted the responsibility and have undertaken to bear the cost, between 1,000*l*. and 1,500*l*., of remedying the mischief. Morally we do not see that the architects were in fault, but moral responsibility and legal responsibility are not always the same thing.

A CAPITAL FROM THE DOGE'S PALACE, VENICE.

SUNDIALS.

A HUNDRED and fifty years ago a knowledge of the methods and calculations for determining the form and details of sundials was a part of the liberal education of every gentleman—or, at least, of every architect, for whom "dialing," as it was termed, was an important part of his professional equipment; and even at the beginning of the nineteenth century dialing was considered a most necessary art, as the liability of clocks and watches to get out of order, go wrong, and stop was held to render essential the provision of some invariable instrument, as a dial. In these days of Waterbury, Ingersoll, and synchronised clocks every schoolboy has a watch, and we do not often need dials for the correction of our timepieces; but an accurate sundial still has its value for a country house some miles from a railway station, and at least forms an excellent feature or opportunity for detail in the architecture of garden or house. It is well, therefore, that architects to-day should know something about dialing.

Although sundials may be made in spherical or hemispherical form, or indeed in any form, the most usual arrangement is that of a plane, either horizontal or vertical, on which shadows are thrown by a wire or rod or by the upper edge of another plane erected perpendicularly upon the former. The horizontal or vertical plane is necessarily parallel to a plane passing through some great circle of the earth, and the shadow-casting edge must be placed parallel to the earth's axis. In the ancient parlance of dialing, the shadow-casting plane is called the "gnomon," its upper edge the "stile of the dial," and the line on which it is erected the "substile." The angle included between the stile and substile is the "elevation" or "height of the stile," and, the stile being parallel to the earth's axis, its elevation is regulated by the latitude of the spot for which the dial is intended. This is the fundamental principle that the dialist must always bear in mind. It is useless, therefore, for our client to pick up an old sundial in a curiosity shop and set it up in his garden in the expectation that it will tell the time when the sun shines. If the dial was originally calculated for the latitude in which it is to be re-erected it may, properly fixed, be all right; if it was not, it will be all wrong.

Our client's antique dial may be correct as regards latitude but still inaccurate, because it is not fixed as it was originally. Usually dials are fixed with their planes either parallel or perpendicular to the plane of the horizon—in other words, horizontal or vertical; but they were not always so, and were then called "inclining" or "reclining" dials, according as their planes made acute or obtuse angles with the horizon. Again, in the case of vertical dials, it is easiest to make them face directly north or south, and often in old examples we find the dial not parallel to the wall on which it is fixed, but projecting from it at one side, so that it might directly face north or south, although its support did not. The ancient expert dialist would scorn such a clumsy evasion of difficulty and make his calculations for a "declining" dial—that is, one with its plane turned away from the north or south. It is evident that we may have combinations of these variations from the normal, and our antique may have been a "declining-inclining" or a "declining-reclining" dial.

There is one more point of importance with regard to the accuracy or otherwise of an old sundial. One often sees people looking at such an ancient work, and checking its record by a watch carefully set to Greenwich time. Finding the two do not agree, they jeer at the apparent incorrectness of the sundial, forgetting that a sundial gives "solar time," which is sometimes a *little* before and sometimes a little after clock time, the variation being still noted in some of our calendars, which inform us "sun before clock—so much." The sundial's time will also not agree with Greenwich time unless the position of the dial is on the longitude or meridian of Greenwich, but will be local solar time.

One should be careful, therefore, in purchasing an old dial with the idea of re-erecting it, to see that it is marked, as some were, with the latitude and longitude of the place for which it was calculated. If these correspond with those of the spot at which it is to be re-used,

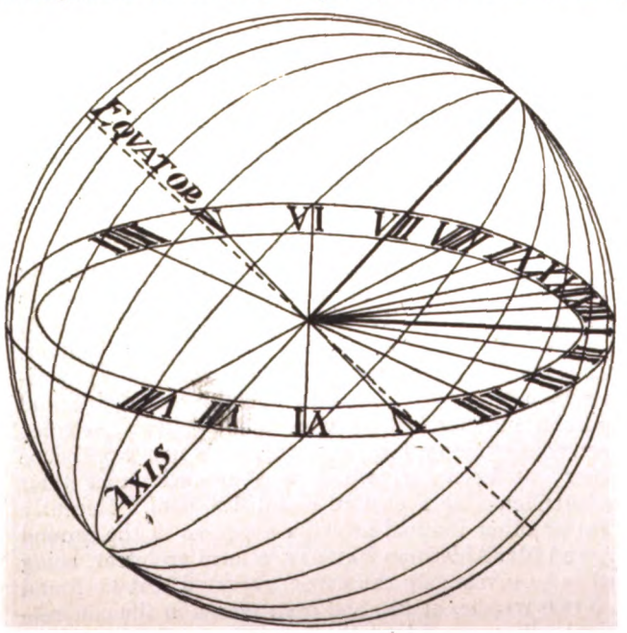

Fig. 1

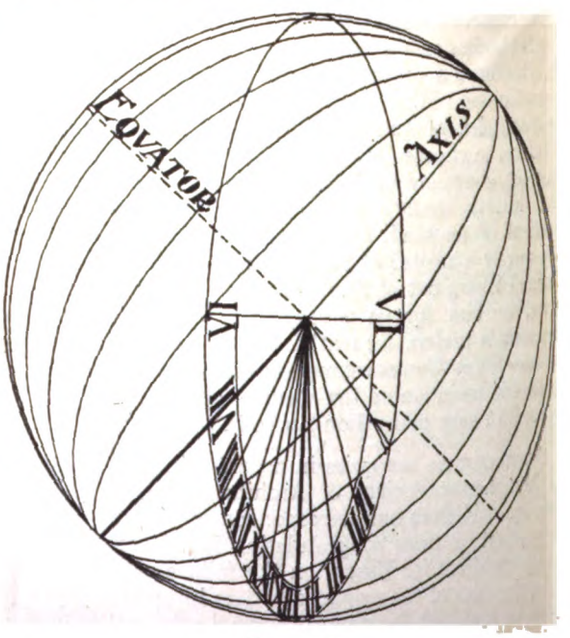

Fig. 2.

Digitized by Google

all well and good, but if not it is hardly worth while trying to alter it, and it had better be put inside our client's house as a curiosity. If the latitude is right but not the longitude, the old dial can still be used with correction for the variation in longitude as well as for the difference of solar and clock time. Knowing the latitude, one can easily determine if the dial is inclining or declining, for the angle that the stile of the gnomon makes with the horizon is the same as the number of degrees of latitude for which the dial is calculated. Thus, the latitude of London being 51½ degrees north, a sundial for London would have the stile of its gnomon 51½ degrees above the horizontal plane; and if we found the angle in our antique dial corresponding to the degrees of latitude, we should know that it was a horizontal dial; if it were equal to 90 degrees less the degrees of latitude—that is, the complement of the horizontal angle—we should recognise our dial as an erect or vertical dial. If the angle does not thus correspond, the dial would be inclining or reclining according to circumstances.

Starting from the fact that the shadow-casting edge or stile of the gnomon is parallel to the earth's axis and its angle with the horizontal plane equal to the degrees of latitude, we next proceed to consider how the "hour-lines," or lines along which the gnomon casts its shadow at the different hours of the day, are to be determined.

Three methods were used by the old dialists for this purpose—by the use of a globe, by graphic calculation, and by mathematical calculation. Of these the use of a globe is easiest, mathematical calculation the most accurate, and graphic calculation the most used, for it does not require the possession of a suitable globe and is easier than the mathematical method.

An ordinary terrestrial globe may be used for dialing, but the old dialists seem to have more often employed a special dialing globe, made with twenty-four brass semicircles of plate or wire joined at the poles and having a thin plate of brass within, as shown in figs. 1 and 2, fig. 1 being for horizontal dials and fig. 2 for vertical. The principle, however, is the same whichever form of globe is used. For example, let us suppose that we are going to use an ordinary terrestrial globe with twenty-four meridian semicircles upon it, then, if the globe is elevated to the latitude of the place for which our dial is intended and turned till one of these meridians cuts the horizontal in the north point, where the hour of XII. is supposed to be marked, then the rest of the meridians will cut the horizon at the respective distances of all the other hours from XII. If, as sometimes is the case, to give ample clearance the horizon ring is at some distance from the surface of our globe, it is advisable, in order to minimise inaccuracy, to lay on the horizon a cardboard ring, cut as close as possible, on which to mark the points at which the meridians cut the horizontal line. This method also has another advantage. Having marked our points for the hours on the cardboard ring, we can lift it off, lay it on a sheet of drawing paper, draw lines from the points to the centre of the circle, and we have the hour lines of a horizontal dial for the latitude with which we started. Our work as dialist is now completed. We have settled the angle of our gnomon, and the angles the hour lines make with the substile, and we can now give play to our powers of design. We can make the plane of our dial any size or shape we please—circular, square, octagonal, or any other that we fancy—simply drawing our hour lines to its edge from the centre. We can make the gnomon any shape we please, provided we keep the stile absolutely straight and do not project beyond it.

We assumed that our globe had twenty-four meridian semicircles marked upon it. If it has any other number we must modify our working to bring the meridian lines we use 15 degrees apart, for the sun moves 15 degrees every hour (or rather the earth does so in its revolution).

In cutting our cardboard ring we must arrange for keeping it clear of the brass meridian that supports the globe, either by making our ring in two pieces or cutting notches out of it.

We can use our globe to find, in a similar manner, the hour lines for a vertical dial, but in this case the angle of our gnomon or the elevation of our globe is the complement of that for a horizontal dial.

Up to the present we have only dealt with direct north and south dials; our horizontal dial must therefore be fixed with the substile north and south, and our vertical with its plane facing directly north or south. In placing our dials in position we must not forget that the true north varies from the magnetic north. The amount of variation is given in nautical and some other almanacs and changes year by year.

(To be continued.)

STEELWORK.—IX.

By C. V. Childs, A.M.I.C.E.

THE architect of a building has the choice of various methods, any of which he may employ in dealing with the design for the steelwork. For example, (1) the design may be prepared in his own office; (2) he may employ a consulting engineer; (3) he may place the work unreservedly in the hands of a steelwork contractor; (4) he may ask various steelwork contractors to prepare designs and submit prices in competition. There is still another method, but the less said about it the better, viz. to make use of one steelwork contractor's design to obtain estimates from their competitors.

Dealing with these methods separately, (1) and (2) are the only proper courses to be adopted as far as the architect's clients' interests are concerned. Some architects are quite competent to prepare their own steelwork design; at the same time, in these days, professional men have been obliged to become more and more specialists. An imperfect knowledge is a dangerous thing in steelwork as in all things else; the designer requires to know not only the theory of stresses and strains, &c., but the practical knowledge as well in regard to the methods of general practice at the rolling-mills and at the constructional works; in the latter case, not only in regard to the workshop practice, but also that of the estimating department and the drawing office; in fact, the whole procedure that takes place from the time the material is ordered until it is erected in position, not to mention the adjustment of the variations and alterations that affect the final settlement of the account.

In regard to the second method, the consulting engineer would naturally wish to have considerably more to say were it not for the restraining influences of etiquette and modesty. Now that the steelwork is the all-important part of the structural stability of important buildings, the engineer should have as recognised a status as, for instance, the quantity surveyor, whose profession is also supplementary to that of the architect. Unfortunately the engineer cannot afford to do his work feeless; the delicate problem is how his fees are to be provided. It would be altogether in the interest of the architect's clients if recognition of the engineer's services were properly acknowledged and provision made in the quantities, as in the case of the quantity surveyor.

It is just as expensive for an owner to erect a building requiring thousands of pounds of steelwork without this having been properly designed as for him to erect a building of similar cost without employing an architect. Even contractors, whether for the steelwork or the building itself, have their faults common to humanity where self-interest is concerned. The only other source from which the engineer can look for payment is out of the fees of the architect himself; this seems to be putting a premium on preventing the architect doing his utmost in the interests of his clients. There is yet another aspect of the case—the engineer would wish to avoid cutting the ground from under the quantity surveyor; but until his own position is a recognised one the fees for the quantities are a temptation, if only for the sake of reducing the amount, the only source of payment for which is from the architect's own fees.

From the writer's own experience the time and labour employed in preparing the steelwork plans is fully twice, or even three times, that of taking out the quantities.

A consideration of the other two methods demonstrates the advantages of the services of an independent engineer.

Digitized by Google

To leave the design entirely in the hands of the contractor is the better method of the two; the design is certainly not likely to err on the side of weakness if the price is arranged on a tonnage basis or on a schedule of prices per ton for the different classes of work. On the other hand, an all-round lump sum price is a dangerous temptation to reduce the strength of the steelwork, even though accompanied by a set of plans, which may often leave a great deal to the imagination. There are tricks in steelwork, as in other trades; for instance, "7"—R.S.J." on the plans may mean either the British standard 7 inch by 4 inch joist or the foreign section 7 inch by 2¼ inch. Again, sizes of girders may mean anything unless it is stated of what sections they are composed; the same also applies to the stanchions; so that it is possible to prepare plans which, as far as information is concerned, are worthless, and are incapable either of being checked or of the tonnage being estimated therefrom.

There still remains the other method to be considered, viz. that of asking various steel contractors for not only competitive prices, but competitive designs as well. Without considering the large amount of work and expense to which the various firms are put in preparing so many designs, this system has serious faults, and penalises those firms who are the most conscientious in preparing their designs. To make an accurate comparison between a number of competitive designs entails as much or even more work to an independent engineer as preparing a complete set of steelwork plans. It must be remembered that it is the plans rather than the prices that are competitive in such cases. The firm whose designer is willing to take the greater risks, thereby reducing the strength of the steelwork to almost the danger point, has the greater advantage over his more scrupulous competitor. Also, not only the sizes of the members may be affected, but the details of construction; the weakness of the steelwork is liable to be due quite as frequently to the latter cause as to the former. Even a stringent specification to form the basis on which the designs are to be made does not overcome the difficulty; rejections of material cannot be made without seriously interfering with the progress of the building.

The chief duty of an engineer in preparing the design is to provide all the information that the steel contractor would require to enable him to make the detail drawings. This can usually be accomplished by means of the eighth-scale drawings, showing the plan of the steelwork at each floor, the schedule giving the sizes of the stanchions, as well as the bases and grillages and the specification, which should be sufficient to guide the draughtsman in making the detail drawings. It is unnecessary for the designer to supply elaborate detail drawings; these are only required in the case of special construction, such as roof trusses, lattice girders, &c. Many a contractor's draughtsman would bear out the writer in the statement that the more elaborate the details supplied to the contractor are, the less the really important information appears to be given. The designer's energies seem to be expended on the details, to the detriment of more important essentials.

In any case, the contractor has to prepare the shop drawings in accordance with the draughting office routine and with his own shop practice, to which his workmen are accustomed. The contractors should be allowed some little latitude in this respect, as all works are not equipped in exactly the same way, and different firms may use slightly different and equally good methods in matters of minor importance. This should not be taken to mean that the contractor is to have an entirely free hand in the matter of the details; by no manner of means. The contractor should be made to supply to the engineer a photo copy of the working drawings, exactly the same in form as those supplied to his workmen, and no work should be put into the hands of the plater until these details are approved; this really causes no delay. At this stage the material is usually on order from the mills, or, if taken from stock, the material can be got out ready for it to be marked out by the plater. The advantages of this system are that the engineer is checking the actual working drawings and that these can be passed on to the architect, who finds them exceedingly useful in preparing his own large-scale details of the decorations. The engineer can usually signify his approval or otherwise to the contractor by return of post; all he is concerned about is that the details are made in accordance with the specification, that the brackets, &c., are amply strong, and that the work is constructionally sound. For the lengths and the proper fitting together of the work the contractor is responsible; any defect in this respect is at once apparent when the steelwork is erected, and must be made good by the contractor.

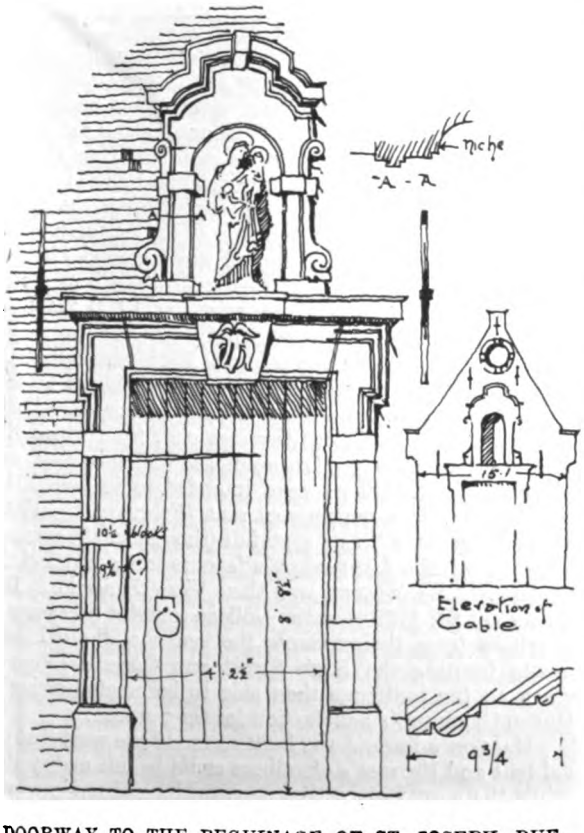
The set of the contractor's working drawings are in this case always available for the use of the architect, the engineer or the clerk of the works in regard to any questions that may arise concerning the steelwork.

It is important that the designer should avoid the use of special sections and adhere to those that are usually stocked or can be quickly procured from the rolling-mills, not only in regard to joists, but also to plates and angles. These three shapes are practically all that are necessary in the design of steelwork for buildings. Channels are convenient sections in special cases, but should not be used extensively; in fact, their use can in general be avoided for main members and confined to matters of detail. The drawback to special sections is that not only are they not kept in stock, but delay is caused by having to wait for the rolls to be put in, and this occurs only between long intervals; whereas with stock sections, even if the stock of these runs out, the demand for them necessitates that they appear more frequently on the rolling programme of the mills. The contractor should not be allowed the opportunity of giving as an excuse for delay in delivering the material that he is unable to obtain the sections from the rolling-mills; even with stock sections this is a favourite excuse on his part, though there may be no cause for it; it is human nature, even amongst schoolboys, to put the blame on someone else. This excuse in some cases may be put forward for ulterior objects which may not be beneficial to the design.

Forgings and all blacksmith's work should also be avoided as much as possible, as this class of work is expensive and the fruitful cause of delay in getting out the work; moreover, the steel is to a certain extent injured in the process unless there are facilities for afterwards annealing it.

(To be continued.)

EARLY ENGLISH PORTRAITS.



ONE of the objects of the Burlington Fine Arts Club is to hold at least once in the year special exhibitions having for their object "the elucidation of some school, master, or specific art." During the past forty odd years the organisers have laid the art of practically all the world and of all ages under contribution. For instance, in the last seven years there have been exhibitions of English mezzotint portraits 1750-1830; ancient Greek art; pictures, &c., of the School of Siena; works by CHARLES W. FURSE, A.R.A. (1906) and ROBERT BROUGH, A.R.S.A. (1907); early German art, the faïence of Persia and the Nearer East. Last year considerable public attention was aroused by the illuminated manuscripts that were brought together. It is rather surprising that the club has never organised an exhibition of "Early English Portraiture" before. At No. 17 Savile Row there are on view now seventy-five works, of which one of the earliest (entitled *Four Scenes from the Life of St. Ethelreda*) is believed to have been executed about 1425; while the latest belongs to the reign of HENRY VIII. The catalogue, which is an authoritative one, for it has been compiled by Mr. LIONEL CUST and Mr. CHARLES F. BELL, of the Ashmolean Museum, suggests that the St. Ethelreda scenes may have formed the doors of an aumbry, and are said to have formerly belonged to Ely Cathedral. The panels cannot be said to show marked skill, and the one showing St. ETHELREDA superintending the erection of Ely Cathedral is of small interest architecturally. The compilers do not venture to give any opinion as to the painter's name or nationality. Perhaps it might be asked as to whether a work of this sort ought to be classed as portraiture, for it is rather unlikely that the artist was troubled as to the necessity of producing a "likeness," or as to accurate historical detail. It is otherwise with HANS MEMLINC's famous triptych known as *The Virgin and Child, with attendant Saints and Angels, adored by Sir John Donne, his Wife and Daughter*, which has been lent by the Duke of DEVONSHIRE. The date suggested is 1468. Though in this case also there is a predominance of the pictorial both in the landscape background and the architectural setting.

Digitized by Google

Royal portraits constitute a large proportion of those exhibited. There are five of Henry VII. and six of Henry VIII. Of particular interest is Holbein's cartoon for part of the wall-painting in the Privy Chamber at Whitehall Palace, which shows the domineering figure of Henry VIII. in the foreground, with his father standing as a servitor behind. This cartoon was the actual one used for transferring the design to the wall and is of the highest importance. Holbein is represented by some fine portraits, including that of his first patron, Sir Thomas More (lent by Mr. Edward Ruth). But most connoisseurs will prefer the miniatures by him. There is some uncertainty as to the authorship of *William West, first Lord De La Warr*; it used to be attributed to Guillim Stretes, but the compilers ascribe it to Holbein. It seems, however, to be unlike the work of the latter. To Stretes is usually attributed the large *Henry Howard, Earl of Surrey*, in which special care has been lavished on the architectural framework in which the nobleman stands; though here also the compilers are unwilling to accept tradition.

Visitors to this exhibition should not overlook the writing room, which contains copies by C. A. Stothard of the paintings in the Great Hall, or Painted Chamber, in Westminster Palace, and drawings made by R. Smirke in 1800 of the wall-paintings formerly in St. Stephen's Chapel at the same Palace. These latter were carried out in the middle of the fourteenth century, and very probably were by Englishmen. The chapel was destroyed by fire in 1834.

The Burlington Fine Arts Club has, according to an introductory note, not met with the success anticipated in organising the collection. It was found impossible to obtain a loan of the portraits in Windsor Castle and Hampton Court. But a valuable series has been got together from other sources. And in any case their absence has made no difference to the prefatory chapters of the catalogue, which give an historical account of Early English portraiture in its various phases of the highest value.

DOORWAY TO THE BEGUINAGE OF ST. JOSEPH, RUE NEUVE DE GAND, BRUGES.
From a Sketch by Banister Fletcher.

QUEEN'S COLLEGE, OXFORD.*

By John R. Magrath, D.D., Provost.

Queen's College, Oxford, was founded by Robert Eglesfield, chaplain to Philippa, wife of Edward III. The patronage of the Queen and her influence with her husband and with the Pope alone enabled Eglesfield to lay the lines of his foundation. He called it after her, and desired that the consort of the reigning king should always be invited to become patroness of the College.

When Eglesfield founded his College, the north-eastern portion of the city was for some reason waste and poorly inhabited, and the site which he secured for it, while corresponding pretty closely with the northern part of where the present buildings stand, extended on the east as far as the city wall, and on the west to the boundary of the parish of St. Peter-in-the-East, where All Souls abuts on the garden of the Warden of New College. Both extremities were coveted by and granted to William of Wykeham, and now form the Warden's garden and the south part of New College garden.

The buildings which were scattered over the site were first put to such uses as they were capable of, and perhaps the earliest building to lodge any of the scholars of the Queen was on or near the site of the present College laboratory. A porter's lodge was soon needed; a handsome Perpendicular gateway, indicated in Loggan's view of the College and pictured in fuller detail in an engraving by Burghers, occupied the site of the gate now opening into Queen's Lane, just opposite the entrance to St. Peter's Churchyard. Over it were rooms, probably originally designed for the Provost, as this was the usual position of the head's apartments in an Oxford College, but celebrated down to their demolition as having been occupied by King Henry V., "Victor Galliæ et sui," the conqueror of France and of himself.

The chapel was near the south-eastern corner of the College. The foundations of its walls and of a magnificent ante-chapel built in 1518 by Robert Langton, Doctor of Laws and Protonotary Apostolic, are under the grass in the middle of the eastern grass-plot in the present front quadrangle. The sill of the great west door of the ante-chapel just reached the western edge of the pathway which leads from the great south gateway through the centre of the quadrangle. A bull for the erection of the chapel was granted at Philippa's request, but care was taken that the vicar of the parish should not suffer from the diversion of his fees and offerings, and to the present day the College makes a quarterly payment to the vicar under the provisions of the bull.

Loggan's print shows the arrangement of the buildings in the old College. The discovery of the foundations of some of them in 1903 testified to his general accuracy. The College at this time was separated from the High Street by a row of small houses, and their yards ran back to the line which then formed the southern boundary of the College. Of the buildings depicted in Loggan's view only those at the north-eastern corner have not been wholly destroyed. Even they suffered considerable modifications to bring them into harmony with the general features which the new College was to assume.

It was, however, the constructor of this building, which occupies the site of the two northern staircases on the eastern side of the back quadrangle, who gave the impulse to the movement for the reconstruction of the College. Joseph Williamson, son of a poor country parson, educated first at St. Bees and then, after a short time spent in London as clerk to a Cumberland M.P., as a town boy at Westminster, entered the College with a recommendation from the celebrated Busby to Provost Langbaine, and rose to be Secretary of State. He never forgot the College, his *Mater alma et cara*, of which he vindicated his claim to be *pientissimus filius*. Besides munificent presents of plate, and influence used with vigour and success to promote its members to posts of

* See Illustrations.

Digitized by Google

dignity and emolument in Church and State, he spent over 1,700*l.* on the building just referred to, and bequeathed at his death, besides a library of valuable and interesting books, 6,000*l.* towards the enlargement or reconstruction of the College. His crest, "Out of a ducal crown or a demi-eagle gules winged sable, holding in his beak a trefoil slipped of the third," still remains on the north wall of the building he erected, and his arms are found with those of LANCASTER and EGLESFIELD on the architrave over the passage leading northwards from the front quadrangle. The demi-eagle was substituted at the time he was knighted for his older crest, doubtless to connect him with the eagles which form EGLESFIELD'S blazon, and the new motto then adopted, "Sub umbra alarum tuarum" ("Under the shadow of thy wings"), is also fragrant of his "singularis erga matrem pietas."

The earliest date connected with the present buildings is 1682, which appears in a chronological list of the works of Sir CHRISTOPHER WREN, drawn up in Latin by one of his sons, as the date at which "Capellam collegii Regin: apud Oxon extruxit." Tradition has, however, always assigned the design of the new College to HAWKESMOOR, who had already by 1682 become WREN'S "scholar and domestic clerk." WREN'S contribution to the work may be embodied in a print by BURGHERS representing an approximation to the present façade of the hall and chapel, but with a fine iron gate closing the chapel passage, which has no muniment room over it, the columns and pediment brought forward so as to form a regular portico, and a very fine lantern in place of the present clock tower.

WREN was at work in Oxford on the Ashmolean building about this time, and HAWKESMOOR was closely associated with him from 1679 onwards, so it probably would be difficult for anyone but the architects themselves to determine their exact contributions to their united work. The general plan of the two quadrangles must have been settled early, before 1682 if BURGHERS'S plate really represents WREN'S design of that date. It was a bold conception, as it involved the removal of nineteen-twentieths of the buildings crowded on a part of the proposed site, and the raising of the whole to the level of the highest part—that on the north towards New College. The High Street frontage belonged to the College, with the exception of a tenement at the south-west corner, which was purchased from Magdalen College in 1709, but the inclusion of the eleven tenements of which it consisted in the site of the new College involved a considerable loss to the revenue from rents.

It was the receipt of the books bequeathed by Bishop BARLOW at his death in 1691 which rendered the provision of a new library necessary. Provost HALTON rose to the occasion, and in May 1692 to the north of the then existing College buildings was laid the foundation of the new library, of which the outside was finished in 1694. The library itself is a magnificent room, 123 feet by 30 feet and 55 feet high, with a splendid stucco ceiling by ROBERTS, and stands upon a cloister which was open to the east and closed to the west, where it fronts the College garden. On this side on each side of a doorway in the centre of the building are niches in which, beginning from the north, are statues of Sir JOSEPH WILLIAMSON, Archbishop LAMPLUGH, Bishop BARLOW, EGLESFIELD, EDWARD III., PHILIPPA, CHARLES I., and HENRIETTA MARIA. The bookcases and manuscript-cupboards are adorned with elaborate wood-carving by GRINLING GIBBONS. The elevation towards the garden is a very successful bit of work. When the new library was built HALTON pulled down the old library, which faced the west front of LANGTON'S ante-chapel, and erected a new range of buildings, part of which was appropriated to the Provost and part to chambers for the chaplains, clerks and "famulus." These had to be removed when the new plan was carried out, but the materials inside and outside were made use of in the new building which took their place. The erecting of the library required the obtaining from the city a portion of Queen's College Lane, and this for a length of 20 feet or thereabouts and about 20 inches wide was granted by the city for 1,000 years on a peppercorn rent (September 2, 1692). This seems to have been the first of the acts of liberality shown by the city authorities towards the builders of the new College. Other similar acts followed, as we shall see further on. HALTON kept elaborate accounts of the building of the library. The cost seems to have been 5,247*l.*, including 178*l.* 1*s.* for statuary by VANDERSTEIN and 16*l.* to BURGHERS for two copper-plates of elevations of the building; the ceiling, by ROBERTS, cost 148*l.* 9*s.* 8*d.* Nine hundred pounds of the total seems to have been derived from timber sold at Heckley, over 1,800*l.* was borrowed from the College chest, 600*l.* came from a legacy and a donation of Bishop SMITH, of Carlisle, and about 100*l.* from other benefactors. About 2,000*l.* seems to have been contributed by HALTON himself, who also gave a good many books to the library. Access to the library was given by a staircase constructed in a small annexe which, according to a view of the library taken before the College buildings were completed (probably one of the copper-plates by BURGHERS mentioned above), stood to the south of the library.

In the plans for the reconstruction of the College the line of the library was taken to determine the position of the west block of the new front quadrangle. HALTON may be thus said to have determined by his building the general plan of the reconstructed College.

It seems probable that it is to Provost LANCASTER, in whose time the legacy of 6,000*l.* bequeathed by Sir JOSEPH WILLIAMSON for the purpose accrued to the College, that the general conception of reconstruction is due. It is, at all events, certain that it was during his provostship that the scheme attained the definite character which it preserved practically unmodified through the sixty years during which, in face of what was for the time enormous cost and endless difficulties, it was gradually being realised.

The College seems to have had before it several designs, which have been preserved, but without any indication of date or of the name of the architect. They all contemplated dealing with the whole space occupied by the present quadrangles, and had all the boldness and variety of the Palladian architects. One filled the whole space between the two quadrangles with an enormous elliptical chapel, which would have added another towering dome to the spires of Oxford.

Taking HALTON'S library as determining the north-west corner of the building and the corner occupied by Sir JOSEPH WILLIAMSON'S new rooms as the north-east, the design contemplated two large quadrangles extending from the lane separating the College from New College to the High Street. This involved the removal of the College's southern boundary 70 feet further to the south. For the erection of the north side of the northern quadrangle the city granted a slip of waste ground 176 feet in length, beginning at the east with a width of 4 feet and tapering to a point at the west, for 1,000 years, at a peppercorn rent (March 20, 1706).

On the south side towards the High Street the city granted a slip of ground out of the High Street 60 feet long, and tapering from a breadth of 5 feet or thereabouts at the west to a point at the east end, "on which slip a front of severall public buildings for enlarging and beautifying the College were intended to be built," for 1,000 years, at a peppercorn rent (February 16, 1709). This was granted "as a gratefull (though small) acknowledgment of Mr. LANCASTER'S favours to the city and the citizens." LANCASTER was then Vice-Chancellor. But it was not till 1733 that the College found it necessary to purchase from their tenants the leases of the old tenements fronting the High Street and Queen's Lane, to carry on the buildings then able to be erected owing to Queen CAROLINE'S benefaction for the purpose.

HALTON'S library was built so far to the west that the old hall and Provost's chambers could be left undisturbed while the west wing of the new south quadrangle was in process of erection. The old chapel was not entirely removed till the erection of the east wing of the same quadrangle was taken in hand. The only modification of HALTON'S library which was effected at the time was the

Digitized by Google

removal of the staircase building and the incorporation of the staircase itself in the arrangements for access to the new common rooms and to the gallery west of the hall. The conversion of the cloister under the library to a storehouse for books did not take place till towards the end of the first half of the nineteenth century, when MASON'S great benefaction made the upper library much too small for the enormous addition of books to be made in the ten years subsequent to the receipt of the benefactor's money.

The accounts of the workmen's wages begin with November 12, 1709, and they are recorded to have begun the pulling down of the old houses on the following December 5. "The west side of the College great quadrangle" was first proceeded with. The first stone of the west wing was laid by LANCASTER on Queen ANNE'S birthday, February 6, 1710. The hall, "being quite finished," was dined in first, Tuesday, May 24, 1715. The date of the payment for the fitting up of the cellar and buttery is given as July 13, 1713; April 5, 1714, as the date of the taking down the slabs from the hall and chapel and other old buildings; July 14, 1714, the kitchen was begun, and October 19, 1716, was the date of the beginning of the arch between the chapel and hall. The west wing seems to have cost nearly 2,700*l.*, and the chapel, hall, kitchen, larder and pantry over 6,100*l.*

(To be continued.)

COMPETITION FOR NEW COUNTY OFFICES AT READING, BERKS.

THIS competition promises to be of a fairly satisfactory nature. An assessor, Mr. MERVYN MACARTNEY, has been appointed, at the request of the County Council, by the President of the Royal Institute of British Architects, and has assisted in the preparation of the conditions of the competition. The amount to be expended is 16,000*l.*, and premiums of 100*l.*, 75*l.*, and 50*l.* respectively will be paid to the authors of the best three designs as placed by the assessor. The County Council reserves the right to select the design best suited for adoption after receiving the assessor's report—that is, they may ignore his award except as regards payment of the premiums. If the author of either of the premiated designs is appointed architect and carries out the work, his premium will be merged in his commission.

The drawings are to be sent in on June 15 next, and are to comprise plan of each floor, front, back and side elevations, longitudinal and cross sections, all to one-eighth scale; detail of portion of front elevation to ½-inch scale; block plan (scale not prescribed) showing drainage. No perspective allowed. Plans and sections "are to be in pen and ink, and may be coloured." Elevations "must be in ink or pencil, and must be coloured" to show materials. Front elevation must be shaded with shadows projected at forty-five degrees.

The problem before the competitors is not an easy one. The site has a frontage of 64 feet to the main street, with a depth of 93 feet 4 inches, and the net floor area of the offices for which accommodation is required is 12,275 feet super, to which have to be added two committee rooms each of not less than 600 feet super. Light is obtainable on all four sides of the site, but not good light except to the main front; some part of the area of the actual site must therefore be allotted to internal courts or areas. A few rooms in the Assize Court buildings are available for incorporation in the new offices, but rather increase than lessen the difficulties of the problem. Briefly, the restricted nature of the site will necessitate very careful and skilful planning in order to provide satisfactorily the required accommodation, whilst the sum allowed for the cost of the building will entail rigid economy, particularly as the employment and remuneration of the selected architect is contingent on a tender being obtained not exceeding the 16,000*l.* by more than 10 per cent. In our next issue we shall give some further information respecting the site and features of the competition.

ARCHITECTURAL COPYRIGHT.

THE following circular-letter has been addressed to members of the Royal Institute of British Architects, and the requests therein contained will no doubt meet with a response from them, but the subject is of so much importance to architects and the art of architecture generally that we would urge all those who can assist the Institute with evidence to offer the same, even though they may not be members of that body:—

Architectural Copyright.

Dear Sir,—The diplomatic conference between the official delegates of the various countries adherent to the Convention of Berne, which was held at Berlin in October last, resulted in important changes being made to certain Articles of the Convention. The British Foreign Office, in consequence of the action of the R.I.B.A., withdrew its previous opposition and adopted the views of the other signatory countries. Architecture has thus at last been accorded its proper place between the sister arts of painting and sculpture (*vide* Article 2 revised), and is recognised as having the same rights to legal protection.

A committee of the House of Commons has been appointed to examine and report upon the proposed changes before the new Convention is ratified by Parliament, and the Council of the Royal Institute of British Architects has been invited to give evidence before this committee. They have accordingly appointed Mr. John Belcher, R.A., and Mr. John W. Simpson (Vice-President), to represent them.

Members of the Royal Institute are reminded that the desirability of protecting the work of architects in the same way as that of painters and sculptors is protected has been urged for more than thirty years by the representatives of the profession in all civilised countries. The International Congresses of Architects at Paris in 1878, 1889 and 1900, at Brussels in 1897, at Madrid in 1904, London in 1906, and Vienna in 1908, have each passed unanimous resolutions to this effect; and similar resolutions have been adopted by the Congresses of the International Association of Art and Letters held at Paris, Madrid, Neuchâtel, Milan, Barcelona, Antwerp, Berne, Monaco, Turin, Liège, Bucharest, Mayence and elsewhere, from 1878 to the present time.

British architects have always been very tolerant towards artistic plagiarism, which may perhaps be considered as a tribute (sometimes awkwardly expressed) by the copyist to the originator; but that deliberate appropriation of an architect's work which it is desired to prevent cannot be defended, and in no way advances the standard of professional knowledge and attainment.

The view it is desired to maintain is, shortly, that the building commissioned by the employer is but a reproduction (in suitable materials) of the architect's design on paper, just as a bronze or marble statue is but the reproduction of the sculptor's sketches and clay models. Both reproductions require the supervision and skill of their designers to bring them to perfection.

It will be remembered that, under the existing legal precedents, the ownership of the architect's sketches, notes, drawings and calculations from which the building is erected is vested in the employer; while the corresponding documents and models of the painter and sculptor are protected.

All members of the Institute who have had reason to complain of the unauthorised reproduction of their drawings, or of their executed work, whether as regards plan arrangement, elevation, or otherwise, are requested to communicate short particulars to the undersigned without delay. Such communications will, if so desired, be treated as confidential.

Expressions of opinion from the Councils of allied societies would, if sent at once, be of great value; and any observations which they wish to make upon the desirability of architects retaining the copyright of their drawings when compulsorily deposited with local authorities (in regard to the execution of architectural work by such authorities) would be opportune at the present moment.—I am, dear Sir, yours truly,

IAN MACALISTER, Secretary.

Mr. John Murray, F.R.I.B.A., Suffolk Street, Pall Mall East, has been nominated by the Local Government Board to value the freehold site of Queen's Road Baths and Washhouses, Bayswater, which the Paddington Borough Council propose to sell, and provide with the proceeds new and improved baths and washhouses elsewhere in the borough. The Council received an offer of 60,000*l.* for the property, and a question arose as to whether this represented its full market value.

NOTES AND COMMENTS.

THE necessity for carefulness on the part of architects in drawing up and arranging contracts with builders on behalf of clients is shown by the result of an action in the Horsham County Court, MYSON *v.* BUCK and BURNAND. EDWARD MYSON, the plaintiff, was a bricklayer employed under contract to do certain work to the premises of Mrs. BURNAND, under the direction of her architect, Mr. W. BUCK. Mr. BUCK seems to have drawn up the contract as between MYSON and himself, and MYSON appears to have been actually paid throughout by Mrs. BURNAND or her agent, Mr. CHURCH, on the certificate of Mr. BUCK or a request to Mrs. BURNAND to pay for certified work. But when a dispute arose as to the payment for extras, Mr. BUCK, the architect, was adjudged to be liable, and he alone. The moral is that if an architect, to save trouble to his client or himself, enters in his own name into a contract with a builder, he cannot afterwards plead that he was acting as agent, but must accept the responsibility for payment of the whole contract amount as well as extras, if his client from any cause fails to pay.

THE Housing of the Working Classes Acts are amongst those that require to be administered with great discretion, not with unrestrained zeal. On the one hand they may lead to the erection of houses that the intended tenants will not occupy except when they mean to pay no rent. This results in heavy charges on the rates to meet the losses on the municipal house property and in depreciation of privately owned house property which has to pay the rates. Throughout the country the experience seems to be general, and housing by municipal authorities is shown to be impracticable. The London County Council has practically abandoned the provision of housing accommodation, and municipal authorities throughout the country are following suit. The Estates Committee of the Sheffield Corporation has adopted the report of its Chairman, Councillor KELLEY, which not only advocates the cessation of building, but the disposal of much land that has been acquired and held vacant with a view to future building operations.

ANOTHER side of the working of these Acts which undue zeal has been shown to render oppressive to the community has been illustrated at Birmingham, where the Housing Committee of the Corporation has been taken to task, and appears to be conscious of its fault of too zealous dealing with small house property belonging to private owners. The requisitions made by order of medical officers of health generally are often not only harsh but unreasonable, and to our personal knowledge call for the carrying out of work quite unnecessary, and contributing in no way to either the health or the comfort of the inhabitants. No doubt there is much small house property, or was at the time the Acts were passed, of an insanitary nature, but it does not pay as well as it did, and for their own protection owners of such property usually find it advisable to make their houses decent and liveable. The fact seems to be that the working of the Acts has directly or indirectly fulfilled their object to a very large extent. There is therefore not enough work now to be done to occupy the energies of the staff of officials brought into being for the carrying out of the Acts, and to justify their existence they have to discover nuisances where none really exist. Our sympathies are with the holders of house property in Birmingham which, though not up to Edgbaston standard, is quite suitable for the tenants that inhabit it, and not at all likely to be rendered more healthy or more comfortable if meddled with by the Housing Committee of the Corporation.

THE case of NUSSEY *v.* The Provincial Bill Posting Company, Ltd., and JOHN EDWARD EDDISON is one of some interest. The plaintiff NUSSEY was owner of one plot and the defendant EDDISON of two adjoining plots on a high-class building estate at Leeds, and, as frequently happens with such estates, there were restrictive covenants binding each purchaser not to do certain things which might prejudice the character of the estate. The character of the fencing to be put up was prescribed, and no noisy, offensive, or dangerous trade was to be carried on. The defendant EDDISON agreed to lease the right of advertising on his plots to the Bill Posting Company, and the company erected for the purpose of displaying advertisements a hoarding 156 feet long and 15 feet high. Mr. Justice NEVILLE, on an application for a mandatory injunction to pull down the hoarding, held that it was a fence other than a fence provided for by the covenants, and also a building for carrying on an offensive trade, and he therefore granted the injunction. The case was taken to the Court of Appeal and decided in favour of the original plaintiff NUSSEY by the Master of the Rolls, Lord Justice FLETCHER MOULTON, and Lord Justice BUCKLEY, all of whom agreed that the hoarding was a fence contravening the covenant, but Lord Justice FLETCHER MOULTON disagreed with the opinion of his two colleagues that it was a "building" within the meaning of the covenant, or that bill-posting was an "offensive" trade.

DR. ASHBY, the director of the British School at Rome, lectured recently on "Prehistoric Antiquities of Malta," of which not a few have been already discovered, and the investigation of which will form part of the director's programme when he goes to Malta this May. Dolmens, hypæthral sanctuaries and burial-places have been found, the latter containing a large number of skeletons and fragments of prehistoric pottery.

ILLUSTRATIONS.

LIVING ARCHITECTS.—NO. 4, SIR ASTON WEBB, R.A.

WE recommence this week our portrait studies of contemporary architects. Sir ASTON WEBB, R.A., F.S.A., acted as President of the Royal Institute, 1902-4, and was awarded the Royal Gold Medal in 1905. He was elected an Associate of the Royal Academy in 1899 and an Academician in 1903.

NO. 5, MR. T. E. COLLCUTT, F.R.I.B.A.

MR. THOMAS EDWARD COLLCUTT, F.R.I.B.A., was President of the Royal Institute of British Architects in 1906-8 and received the Royal Gold Medal in 1902.

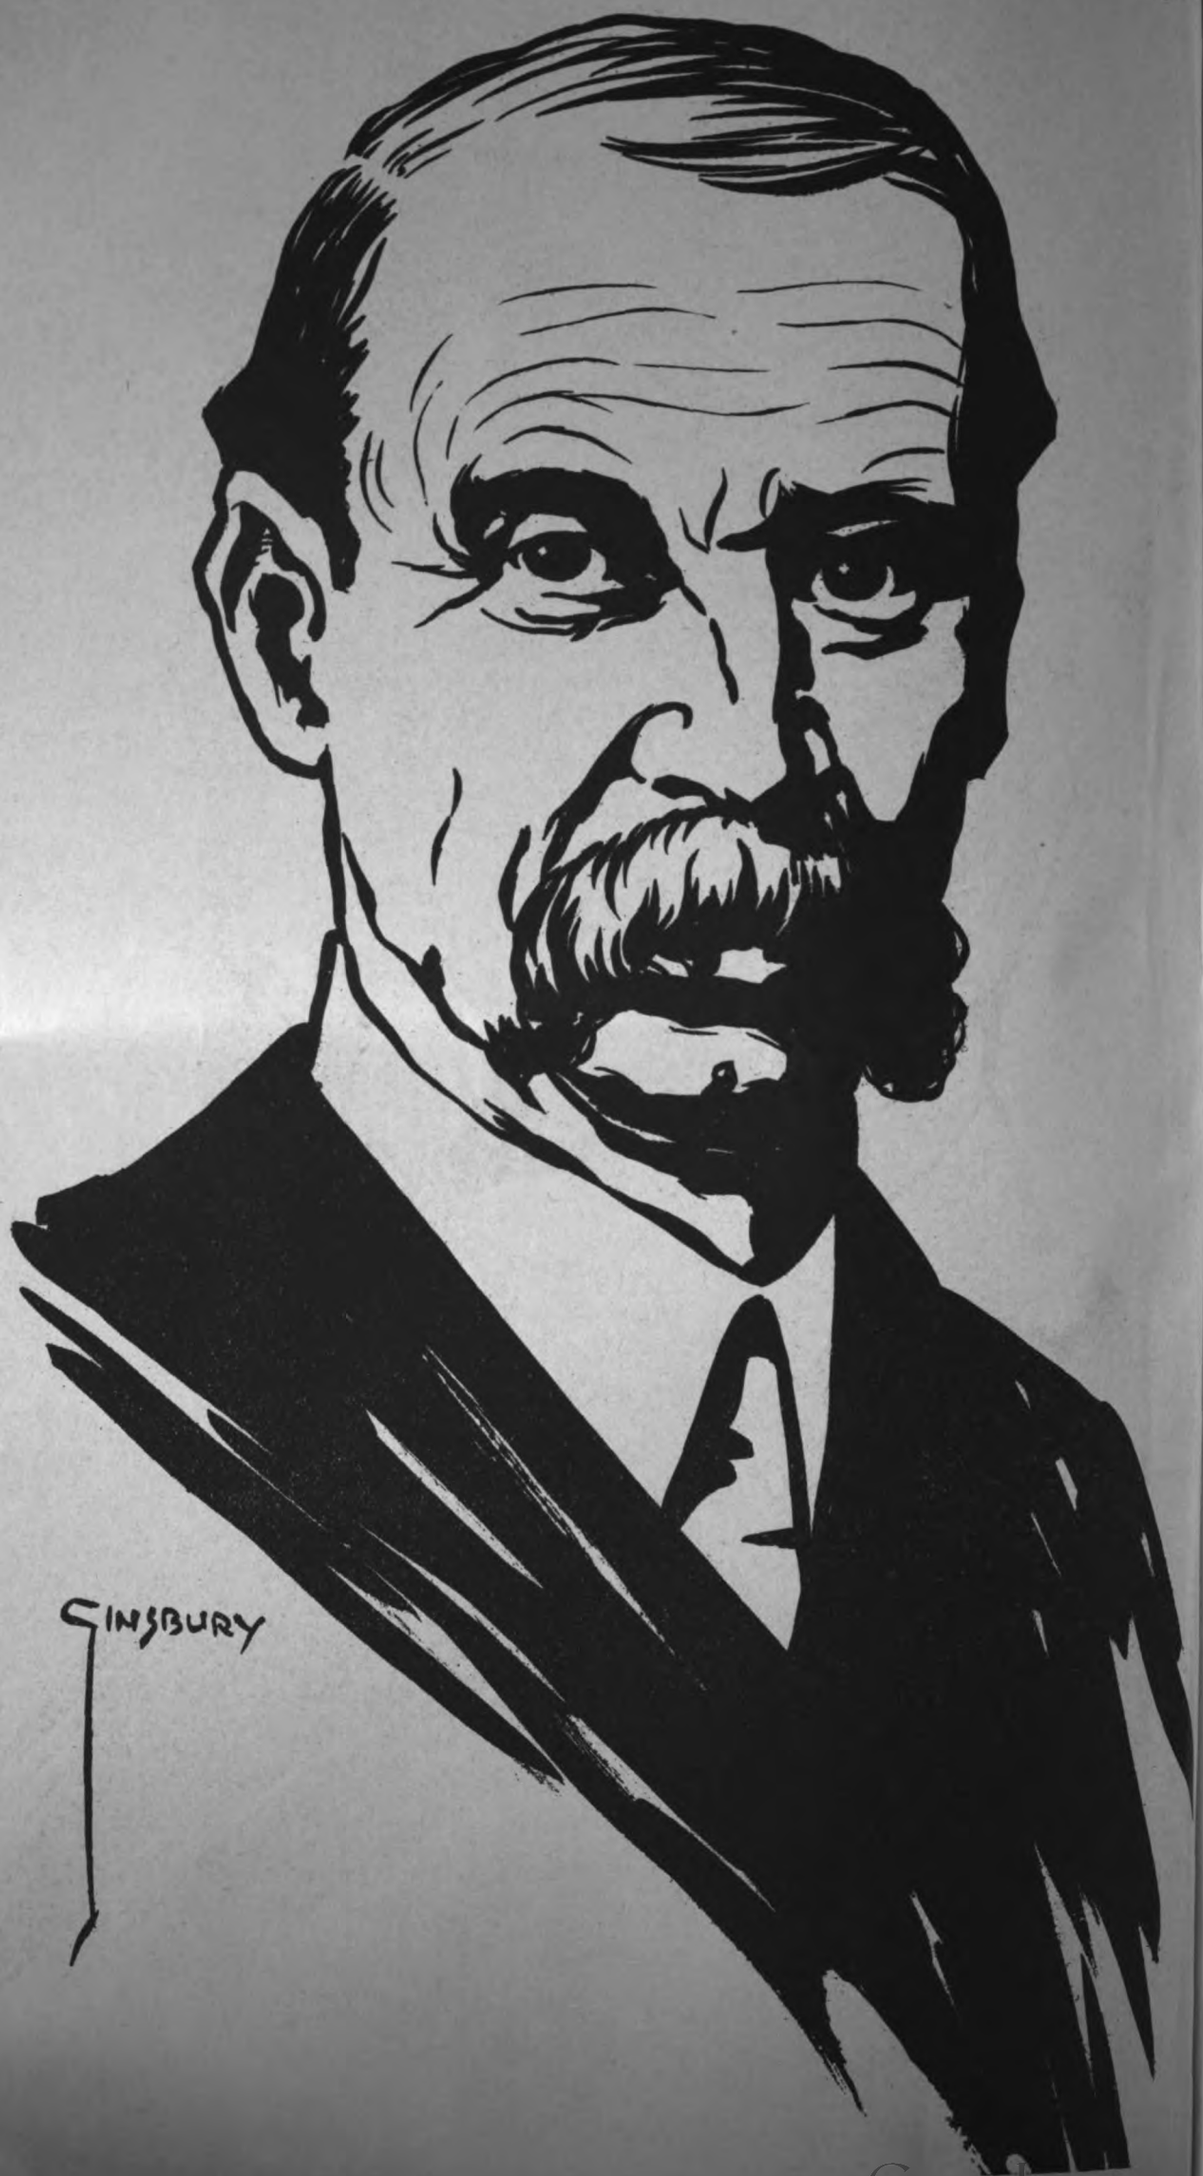
STOCKPORT TOWN HALL.—THE COUNCIL CHAMBER.

THE town hall, which was opened by the PRINCE of WALES last year, stands in Wellington Road South. All the principal rooms communicate with one centre known as the "Council ante-room." The Council chamber is placed on the south side of it, and is 46 feet long by 33 feet wide and 37 feet high, with an enriched dome. On plan the room is a parallelogram, with further space for the public. The walls are treated with Austrian wainscot oak up to a height of 7 feet 6 inches. The mayor's daïs and table are carved after the GRINLING GIBBONS style. The floor is in oak. The electroliers were specially designed, and are executed in gilded cast bronze. The authorised expenditure on the entire building was 100,000*l*. The contract was carried out by Mr. JOSIAH BRIGGS, of Stockport. The architect was Sir A. BRUMWELL THOMAS.



THE CENTRAL STATION HOTEL, GLASGOW.—THE LOUNGE.

THE walls are panelled with Austrian oak and the floor is laid with various coloured marbles. The columns supporting the dome are of Pavonazzo marble. The peculiar elliptical shape was the outcome of the plan of the station offices which occupy the ground floor. The enriched plaster work of ceiling and dome was executed by the Bromsgrove Guild, Bromsgrove. The contractors for the oak work were Messrs. P. & W. ANDERSON, Glasgow, and the marble work was executed by Messrs. GALBRAITH & WINTON, Glasgow. The glass work of dome was executed by Messrs. OSCAR PATERSON & Co., Glasgow. Mr. JAMES MILLER, A.R.S.A., F.R.I.B.A., is the architect of the hotel.

DECORATIVE IRONWORK.

MR. STARKIE GARDNER delivered a lecture on the 7th inst. at Carpenters' Hall, dealing with the above subject. He commenced by observing that the woodworkers' and the metal-workers' crafts are sisters; but there has always been an incompatibility of temper—the fault lying with the metal-worker who has uniformly been the aggressor. The antagonism is not at all personal, but just in the nature of things. There are many purposes for which wood or metal can be used indifferently, and the smith began very early to encroach on the domain of the sister craft. The carpenter loves the smoothness, the texture, and the colour of his woods so much that if he must use any of the smith's productions he mortices them away out of sight, regarding their presence as a blot and an intrusion. On the other hand, the smith merely regards the wood as something of no importance, to light his fires with, and at best to fix his scrolls or diapers upon; he so covers the surface that the wood really does not count. Thus he has made all sorts of things, bedsteads and casements, screens, palings and gates of iron, where they were formerly made of wood. But this is only a foreshadowing of what has been done by the engineer, for the list includes joists, railway stations, bridges, jetties, ships and winter gardens. Then the carpenter's stronghold was attacked, and entire buildings are made of iron. The carpenter may, indeed, be excused if he thinks to himself that for ages the world has got on very well without the engineer, whose presence only makes his own struggle for life harder than it would be.

The smith probably had a good start in mediæval times, when metal-working was the relaxation of saints and kings. No other material except ivory was so richly worked. In those days iron was produced in small blooms, weighing but a few hundredweights. The smith cut off pieces and beat and hammered them out while hot into the shapes he required, and then welded them together to form his hinge or handle; the front face was chiselled and scored with lines forming geometric patterns. Grilles of iron, introduced in the eleventh century, were of similarly rich and involved scroll or geometric patterns. In the days of Edward I. stamps and dies were introduced which could be impressed on the hot iron by blows of the hammer. The effect was that of rich moulding in relief, somewhat resembling cast iron, but retaining the properties of wrought iron. Though the possibility of heating iron till it liquefied and could be poured into moulds was familiar to the Greeks, it remained unknown in Western Europe till the time of Edward III. The richly worked surfaces of the iron in relief, and the intricate designs into which it was wrought had a magnificent appearance when gilded and laid over blue or scarlet backgrounds. After this advance smithing presents little further interest for a time.

About a century later vertical iron palisading, known as railing, was originated in England. Its first use was as a protection for the costly royal tombs. The monuments of Edward the Black Prince and of Henry IV. at Canterbury were palisaded with vertical bars united at the top by heavy and enriched battlemented cornices. Six tall and massive standards confer strength and dignity, and with their turret-like tops and buttresses, represent the great mystic candle-holders of the catafalque. Soon the vertical bars were carried upwards and sharpened into points. Smiths elaborated these spikes and standards, adding to the latter crests and bannerets. These were the precursors of the endless series of vertical railings which became peculiarly characteristic of the architectural ironwork of this country. But the smiths were in demand for sterner duties, and their entire energies became directed to supplying munitions of war.

The withdrawal of the smith from competition was the carpenter's opportunity, and the monopoly he gained remained unchallenged till the reign of Queen Anne. Even the traditions of smithcraft seem to have been completely forgotten, for when a door or screen had to be in iron for security the smith not only took his designs from the joiner, but actually pieced his forgings together with tenon and mortise. There is an excellent example of this work in the screen to the chantry of Henry V. Edward IV. intended to be commemorated by a great metal monument with a rich grille; but no English smith could make the latter, so it was ordered abroad, and is now at Windsor. This remains, though no longer gilded, the most marvellous specimen of iron joinery in Europe. Henry VIII. was more fortunate, for his intention was fully realised. Torregiano made the gilded metal effigies, and the grille was made in London. It was of brass, because no smith in England could have executed it in iron.

No revival of smithing accompanied the introduction of Renaissance architecture into England. Elsewhere, especially in Germany and Spain, smiths were employed on magnificently decorative and costly works, while here only the most homely requisites were wanted. Foreign craftsmen had been attracted to England in great numbers to the discouragement of native talent. Nor did the introduction of Palladian architecture by Inigo Jones improve the outlook, for it does not appear that he ever designed or made use of decorative ironwork. That associated with Wren's buildings, under the Stuarts, is of the plainest description, for smithing seems the one craft in which he showed no interest or concern at all.

No real revival took place until the accession of William and Mary, and when it came it was entirely due to one man. It is rarely granted to an individual, however great his personality and artistic power, to leave his own lasting and comprehensive impress on art. But this fell to the lot of Jean Tijou, a worker in iron, and magnificent designer and craftsman. His work can be recognised by its quality, and with certainty owing to an elaborate book of his designs, and also through the building accounts of Hampton Court and St. Paul's. Practically nothing is known about him. Presumably he was one of the French Protestants who fled to Holland in 1685, on the revocation of the Edict of Nantes, and came to England three years later with, or not much later than, William and Mary. His book of designs was "sold by the author in London" without other address, and his daughter married the well-placed artist Laguerre in St. Martin's-in-the-Fields.

We first hear of Tijou through his bill, entered in 1690, among the accounts for the rebuilding of Hampton Court, for six richly wrought-iron vanes and a wrought-iron balcony, "in finely wrought leaves and scroll-work," overhanging the river. This specimen of Tijou's skill must have been continually under the Queen's notice, and he seems to have quickly gained her goodwill. Schemes and designs for works in iron of unprecedented richness were presented to her and accepted, apparently, without intermediary or estimates. These form the subject of most of the plates in the costly book of designs, engraved on copper by the best artists of the day, published by him in 1693. The garden screen, the most superb ever made, was completed and charged for in 1690, "for the circle of the Fountain Garden at Hampton Court." Another of his bills, for 1,115*l.* 12*s.* 6*d.*, comprised the three rich and still perfectly preserved gates, filling the archways of the east front of the palace. He had commissions for work of no less richness from the owners of Chatsworth, Burleigh, and Wimpole, while the work for St. Paul's, likely to extend over many years, was just commencing. This great prosperity was short-lived. In December, 1694, the Queen died, and all work was at once abandoned. It was not resumed until the destruction of Whitehall by fire, four years later, decided the King to make Hampton Court his principal residence. Of the unexecuted works designed for the Queen, one only, the King's staircase balustrade, was required from Tijou. The alterations necessitated a railing 1,400 feet long to the east front of the palace, the cost of which, and perhaps the design as well, were got out by Talman, who estimated the weight at nearly 46 tons, and the cost at 5*d.* per lb. Tijou, unfortunately, took the contract and rendered the bill for 3,675*l.*; whilst on Talman's figures it should only have been for 2,194*l.* 18*s.* 6*d.* Probably the difference was never certified for payment. The King died in 1702, and Anne, who did not care for Hampton Court, was deaf to appeals. The Royal patronage and with it that of the Court was withdrawn. Tijou removed his works from Hampton Court, and worked for St. Paul's till 1711, but here he was subject to competition, and his total payment extending over twenty years, did not exceed 4,000*l.* He retired abroad, leaving his wife a power of attorney, to collect the balance due on the St. Paul's work; and this was paid in 1712. The tradition extant in his family is that he died broken-hearted.

Whether, as a foreigner, Tijou's memory should be commemorated in London is for others to decide; but we must be fair to it. The statue on the exterior of the new Victoria and Albert Museum, selected to represent smithing, is of a person named Huntingdon Shaw, from Nottingham, who was perhaps not a smith at all, and about whom very little is known. The scanty information might be equally well interpreted as pointing him out to be a stone carver or contractor at Hampton Court. If Tijou, who spent his working life in England, and of whom we have a portrait, is not to be commemorated, his honours should not be appro-

Digitized by Google

priated without reason by a dubious smith. There are many other smiths, his contemporaries, who have a right, Tijou being passed over, to occupy the position. Three of his assistants achieved fame in different parts of the country. The work of each is perfectly distinctive and easily recognised; but all agree in making a lavish use of acanthus and rosettes, in the manner of Tijou, though all equally fail when aspiring to higher flights, such as masks.

Thomas Robinson, who carried on works at Hyde Park Corner, is first heard of as a competitor of Tijou's for the work at St. Paul's, where he executed some beautiful ironwork between 1699 and 1711. His gates are designed in different proportions to those of Tijou and his school—being more lofty and transparent. His use of acanthus and other embossing was always sparing, and its execution and drawing poor.

During the time of Tijou and his immediate successors, and while Wren lived, designing the work had been as essentially a part of the smith's work as its actual production. If the more daring flights of some occasionally lay the artists open to criticism, their work is always grand and impressive, and as expressive of the best English Art as contemporary architecture and painting. The essentially English treatment of Robinson and his school is most refined, and never approaches the commonplace or vulgar in design. This school was rapidly developing along the best lines when in 1728 Gibbs, in his book of architecture, claimed the designing of ironwork to be within the architect's domain and banished craftsmen's designs from architecture as effectually as Kent had banished it from the gardens. Owing to this, the great smiths who followed Tijou left no equally important successors. The gates and window grilles to the Radcliffe Library, the screen to the forecourt at the Horse Guards, and grilles to the Mansion House and Bank of England, are examples of architecturally designed ironwork. Little by little the craftsmen were left nothing to design, until finally the Brothers Adam designed the entire decoration, and also the contents of the houses they built. Thus the "maitre ornemaniste," or professional craftsman-designer, the very originators of all applied design, were finally squeezed out of existence. It seems probable enough that the almost utter collapse of all Art in the country within a few decades in the Early Victorian days may be traced to the suppression of the artist craftsman. It must be conceded that no one should be more qualified to design for the applied arts than the properly trained masters of the crafts concerned in them; and also that not every born designer, now or in the past, is able or wishful to practise architecture.

NOTES ON BOOKS.

"Introduction to the Chemistry and Physics of Building Materials." By Alan E. Munby, M.A. (Cantab.), A.R.I.B.A., &c. (London: Archibald Constable & Co., Ltd. 6s. net.)

VITRUVIUS says "architectura est scientia pluribus disciplinis et variis eruditionibus ornata," and the truth of his assertion holds good to-day; therefore the chemistry and physics of building materials are by no means subjects that are outside the architect's province. Hence a book dealing with them, and written by an architect who is also a chemist, should be welcomed. All architects ought to have learnt something of chemistry and physics before they left school, and had they done so the first part, comprising ten chapters out of the twenty-six in the volume, would have been superfluous; but as these branches of knowledge have often been overlooked by schoolmasters, who seem to think that an architect is only a man who draws palaces and cathedrals, too many young architectural students will find it advantageous to have something of the fundamentals of physics, chemistry and geology explained. As the book before us is professedly an "introduction," one ought not, perhaps, to be too exacting on the author, but we think his book would have been more valuable to architects and architectural students if he had omitted much that is included and is to be found in any decent text-book on building materials, and in the place thereof had given us the chemical tests that are useful in determining the nature and quality of building material. For example, Mr. Munby's account of the gum-resins used in varnish is less full than that in the usual text-books, and does not tell us how we can distinguish a true "copal" varnish from "hard oak." He does not even include in his reference to the adulteration of paint the simple test with a bright silver coin for determining whether a sample of white lead is "genuine" or "best." By revising his second edition on the lines we have suggested we think that Mr. Munby will increase considerably the usefulness of a book that is much needed by architectural students.

"A Complete Guide to Heraldry." By Arthur Charles Fox-Davies, of Lincoln's Inn, Barrister at Law. (London and Edinburgh: T. C. & E. C. Jack. 1909. 10s. 6d. net.)

While in so many and such varied forms of excellence books on this fascinating and inexhaustible subject have appeared from time to time, each presumably seeking to further public interest in and study of it, it is certain that there is even yet a place open to all of them, and this latest fine volume is, if the last, certainly not the least. Exception might perhaps be taken to the word "complete" in its relative sense, inasmuch as, with the numerous similar books of all ages and sizes lying before us, there is even yet much to be done before the last word on this subject has been spoken or written. This is not a dry-as-dust book, but one that turns hard facts into interesting data. Sixty years ago heraldry, if studied at all, was taken up by the very few; to-day it affords much interest and delight to very many; even those who do not follow it up seriously find pleasure even in the casual application of its pictorial side, though only the savant can know what such people lose by leaving out the historical one. We have but to reflect for a moment to feel assured that much of the vulgarity, combined with ignorance of all historical design, in the coach-painting and the hatchments of the long ago, often excellent as handicraft, but of poor art as they were, was caused by the very paucity or non-existence of such books as the one under review. When folk are guided into wrong paths, or find their way to them through the lack of guidance altogether, they deserve as much sympathy as blame. If there be any side of the subject rather scantily dealt with, perhaps the long and vast connection of it with ancient glass might be selected, but every book has its strong and weak points, and in this one the strong certainly predominate.

Changing fashions are not unknown even amongst heralds. We well remember the *canton* being dogmatically instructed to be drawn as fully a quarter of the shield by a high authority, who well knew that the former was clearly in evidence in early days upon more than one monument to his own family then, and still, existing.

With nearly 650 pages of matter and some 800 drawings, many in colour, before us, we cannot refrain from touching in detail upon a few of them. The first illustration, appropriately the arms of our own well-beloved Sovereign, in correct blazonry, sets a high standard of excellence, which is well sustained all through the course of the book. The Union Jack and its historical development are made clear and interesting, both by illustration and letterpress, as is also that old form of pride the vexed question of the "seize quartiers"; deeply interesting, too, is the contribution towards the account of the "pallium" in the arms of the Arch-See of York. However elaborate in line, good heraldry in the main was simple as to the number and character of its charges, and, as a rule, sparse in the variety of its tinctures, and in the best evidences and examples fairly simple in "motif"; as a contrast the coat of Gaveston was well suited to the popinjay who assumed it. One is pleased to endorse the remarks on the heraldic treatment of the Pelican; we have seen her "au naturel" in an ancient religious picture, but never so when applied to coat armour. This fact recalls a chat on this very point with Charles Boutell in the long ago. "Marshalling" has been specially well done, as has also the elucidation of the methods of production of that complex subject, the proper arrangement and portrayal of the pedigree. One item of special interest, if only as indicative of the labour and original research both qualitative and quantitative of the author (see page 79) regarding the "fur" slipper of Cinderella, is worthy of mention. We had never even heard of this version till told it by an English pedestrian while sojourning some years ago at Beauvais. The nettles in the coat of Mallerby are also a rare contribution in canting heraldry. The tabard of Sir William Dugdale, which we saw and handled many years since in the house of a descendant of his, is well illustrated.

There are even yet in much modern heraldry ignoble forms requiring revision. We are reminded of many Austrian eagles displayed in that country irreverently pointed at by our travelling companion, and profanely described as "the rooster." The well-described and illustrated chapter on crowns and coronets merits special commendation.

Without indulging in invidious comparisons, this latest of many fine volumes by Mr. Fox-Davies, fully illustrated and well printed as it is on good paper (a factor in these days), procurable, too, at a price within the reach of any earnest student, reflects nothing but credit on author and publisher alike.

"A Classified Catalogue of the Works on Architecture and the Allied Arts in the Principal Libraries of Manchester and Salford." (Manchester: At the University Press. London: B. T. Batsford. 3s. 6d. net.)

The two editors of this catalogue, Mr. H. Guppy, M.A., and Mr. Guthrie Vine, M.A., librarian and sub-librarian respectively to the John Rylands Library, are fully entitled to regard their handiwork with considerable complacency. They have done something that ought to have been done elsewhere and which will, we hope, be the forerunner of similar undertakings in other cities, including those nearer the metropolis. In 1904 the Joint Architectural Committee, which is composed of representatives of the University of Manchester, the Manchester education committee and the Manchester Society of Architects, appointed a sub-committee to take steps for the issue of a catalogue giving the architectural books in the local public libraries. It was felt that insufficient advantage has been taken of the fine collection that is scattered about the city owing to the difficulty the students meet with in placing his hands upon a book that is not included in the library at which he first applies. The sub-committee first obtained from the various libraries a list of their books dealing with the art. These were next passed on to the editors, who found that considerable revision was necessary. In constructing the catalogue they elected to arrange the entries in a logical or classified order, and then to supply alphabetical lists of the authors and of the particular subjects dealt with. The decimal system of classification, originated by Dr. Dewey, an American, has been utilised, though with some modifications. A concise explanation of its working is given in the introduction. The first 190 pages are composed of the classified list; in it the first heading is "Building Construction" and the last "Architectural Design and Decoration." But this rather unusual order need not bewilder the inquirer, for the prefatory seven pages, headed "Scheme of Classification," will enable him to quickly discover the page giving the books he desires. Then follows an alphabetical author list, and finally a subject index. The compilers have in many ways done a useful service, one of which, and that not the least, is the discovery of what the co-operating libraries have not got. When this omission is important an asterisk is prefixed to the title, so that the authorities may know what works they ought to obtain. The Classified Catalogue will, we have no doubt, have a far more than local use, and it should be an encouragement to librarians to render a similar service to students of other subjects besides the Mistress Art.

"The Chadwick Lectures." Session 1907-8. University of London. By W. D. Scott-Moncrieff. (London: St. Bride's Press, Ltd.)

Sir Edwin Chadwick, K.C.B., after serving on various Commissions in the middle of last century which dealt with existing social conditions, made sanitary reform the work of his life. Anxious that his ideals should not die with him, he left an annual income of about 885*l.* to be devoted to the promotion of sanitary science. The establishment of the Chadwick Lectures at London University is part of that scheme; and the booklet now under notice is made up of four lectures delivered in May last and entitled "The Engineering Aspect of Recent Advances in connection with Sewering." Mr. Scott-Moncrieff has gathered together a large amount of information concerning a subject that is of vital importance. The lectures embody the almost continuous work of seventeen years in originating and developing the science of biolysis, and have all the weight of the author's reputation as a sanitary engineer in the highest meaning of that title.

"Text-book of Petrology." By F. H. Hatch, Ph.D. Fifth edition. (London: Swan Sonnenschein & Co., Ltd.)

In a recent note we referred to the importance of expert knowledge for enabling an architect to distinguish between good and bad granite, and to recognise the accordance or divergence of sample and bulk. This expert knowledge is based on petrology, for chemical composition of stones is not in itself sufficient for their determination. A text-book of petrology is therefore valuable to architects who desire to become experts in granite, and Dr. Hatch's book is an excellent guide to the structure and classification of igneous rocks, whether plutonic, hypabyssal or volcanic. Whilst the author professedly deals principally with igneous rocks, the description of constituent minerals embraces those found in the sedimentary rocks, hence it is useful as an introduction to the further study of these more widely used building stones. The appearance of a fifth edition is sufficient evidence that Dr. Hatch's text-book is of recognised value.

"Illuminating and Missal Painting on Paper and Vellum." By Philip Whithard. (London: Crosby Lockwood & Son. 4s. net.)

Save as a means of embellishing testimonial addresses and delineating achievements of arms it might be supposed that the subject of this little book is a lost art, but the beauty and charm of Mediæval work must not infrequently tempt many an artist to emulation of that work as a recreation if not as a remunerative employment, inspiring a wish that he knew something of the technique. For the technique of illuminating is not that of ordinary body colour painting, and Mr. Whithard has evidently studied carefully the instructions that have been left for us by the ancient artists, and, having put those instructions into practice, has learnt what he now imparts—the right technique for illuminating and missal painting. To the young architectural draughtsman the chapters on writing, with the descriptions of the ancient scripts and the pen forms by which they were executed, are alone worth the price of the book. There is much, too, in the advice and hints given on painting that are of wider usefulness than in the limited field for which they are primarily intended by the author.

AN INTRODUCTION TO THE STUDY OF STAINED GLASS.*

IN a lecture on "The Education and Character of the Architect," by the late Professor Donaldson, the following passage occurs:—

"For my part I cannot consent to restrict the pursuits, the acquirements, the knowledge, the talents of an architect to the narrowed limits of the immediate branches of professional science. This may do for the mere mechanic, but by such a rule the architect as an artist and a man of science cannot, ought not, to be measured. Regard him as a man of science. Is his attention to be merely turned to the choice of this or that timber, the selection of this or that metal or stone? Would I not rather let his mind be more amply developed by diving into the mysteries which regulate matter in general, and by observing the geological structure of the globe and the relative value of each stratum? Shall he not with the aid of chemistry deeply study the stupendous influence of heat, upon which in its largest scope depends the very existence of this sphere? And in the same manner, through every division of physics, shall he as an artist limit, as some have done, his knowledge of architecture to a delineation of the Classic orders, and not rather master all the styles of all ages and countries; profoundly investigate the elements of beauty, fitness and proportion in each; and perchance create a new style or design a new order? Shall he not appreciate the brilliant aids which sculpture and painting afford to buildings, and by the study of colour produce graceful combinations of harmonious tints in the adoption of various toned marbles and the delightful illusions of stained glass?"

It is precisely upon the perfect adjustment of science and art that all crafts depend, and it is this theme I propose to develop this evening. I should prefer therefore to call this paper—

An Introduction to the Study of Stained Glass,

with

I. A description of the manufacture of glass from the raw material, and

II. An account of the various processes undergone in the making of a stained-glass window, concluding with slides.

The question that had first to be solved in my mind, before attempting to formulate some ideas for this paper, was this, What do students of architecture want to know about the subject of glass? Students of architecture, I understand from an eminent architect of very ancient days, "should have that perfect knowledge of each art and science which is not even acquired by the professors of any one in par-

* A paper read by Mr. James Ballantine before the Edinburgh Architectural Society.

Digitized by Google

ticular." I am glad, however, to note that that good and great man Vitruvius maintains "that although it is required of the architect to be generally well informed, it is manifest he cannot hope to excel in each art." My aim, therefore, will be to add to your already replete store-house something that may enable you to feel more qualified for a profession that seems to demand knowledge exact, specific, and progressive.

The historic and æsthetic aspects of stained glass have been considered so often, beginning with Pliny's record that glass was first discovered more than three thousand years ago, together with ample proof of a history as ancient as pottery or bricks, that I want instead to treat the whole field of glass from an intimate individual point of view and to show examples that will illustrate the points emphasised.

I. *Manufacture of Glass.*

Two or three hundred years ago the chemists held that every substance could be converted into glass by intense heat, and that all the chemist's art and all the force of fire could not carry the change of any natural body beyond its vitrifaction. One old writer says:—"It was a merry saying of a very great artist in the business of glass, that their profession would be the last in the world, for that when God should consume the universe with fire all things therein would be turned to glass."

An old definition of glass was "a concrete juice," and the most modern term, used to describe its exact structure observed by delicate instruments, is "congealed liquid," because the passage from a molten liquid condition to a solid is gradual and continuous, no change whatever taking place.

Chemical analysis of all ingredients must be made for the production of the best varieties of glass, and the variation in the colour, &c., cannot be accounted for or controlled unless steps are taken to keep the materials as constant as possible. Briefly put, the principal constituents of glass are sand, with some salt of soda or potash, but when technically stated the raw materials are grouped, as Mr. Walter Rosenhain points out, into sources of silica, sources of alkalies, sources of bases other than alkalies.

The chief source of silica is sand, which is found in France, Germany, Belgium, and England in various states of composition and degrees of purity. The sand from Fontainebleau and Lippe is delivered commercially with a guaranteed silica content of 99-98 per cent., the impurities being iron, alumina, lime, and alkali; while from Belgium and England—in Bedfordshire and Lynn—with a somewhat lower standard of purity, quite suitable sand is obtained. Sandstone and flint are other sources, but the expense of crushing, &c., makes them prohibitive, although in the old days flint was largely used and we still hear of "flint glass."

Originally the alkali constituents of glass were derived from the ashes of plants and seaweed or kelp, but the necessary alkalies are now introduced in the form of sulphate of soda or salt-cake, and for special glass carbonate of soda or soda ash.

The other bases are calcium oxide, or lime and lead oxide, arsenic, manganese, aluminium, and carbon.

These then are the raw materials of glass, and we must now look for a little at the structure of the vessels into which these materials are put. The greatest care has to be taken not only with the materials and making of the crucibles or pots for holding the molten glass prior to blowing, but also with the construction of the furnace for melting the glass.

The pots must be made to last a long time and in such a way that they are not acted on by what is called the "frit"—*i.e.* the raw material. They are made from the most refractory clays, and great care is taken in their building up, the process of drying sometimes lasting a whole year and always many months.

The glass-melting furnace is also made of refractory material, Dinas bricks being much used. The introduction of gas heating into the glass industry has altered the entire method of procedure, and now glass tanks above the furnace are used capable of holding 120 to 180 tons of glass in the case of bottle glass, and 500 to 600 tons of glass for windows.

In coloured glass of pure quality these tanks are of little use and pots are employed, holding about a cwt. of glass metal, which can readily be removed by the blowers with their pipes. The raw mixture having been introduced into the tank or pot furnace, we must now pass over the extremely complicated chemical reactions that take place between the silicates, the alkalies, and the other ingredients. Many interesting processes—viz. the making of bottles, all hollow-ware, rolled glass, pressed glass, wired plate-glass, &c.—must also be omitted in order that we may proceed to the making of sheet glass as being the stage nearest to that of antique glass, which is so largely used in stained glass windows.

Groups of three workmen carry out the various operations connected with the blowing of glass—a pipe-warmer, a gatherer, and a blower. The pipe-warmer's duty is to see that the blowing pipe is of the right temperature, free from dust or obstruction, and to place the pipe in the furnace so that the next workman, the gatherer, may be able at once to begin collecting the molten glass on the end of the pipe. Three separate gatherings are made, each time more glass being acquired, and then the pipe, with its adhering mass, is removed from the furnace and passed to the third and chief workman, the blower. The blower stands on a sort of platform in order that he may have freedom to swing the pipe like a pendulum, more depending upon this than upon the actual blowing. From a bulb shape the mass becomes cylindrical, closed at the lower end. This end is opened either by heating until it gradually softens and bursts open or by touching the end with hot glass and cutting a hole with a special implement. By spinning the blow pipe with the glass attached rapidly, the cylinder, which is now somewhat like a "muff," as it is indeed called, becomes more opened out and can now be detached from the pipe by a piece of cold iron. It is then laid on a wooden rack and allowed to cool slightly before being opened out into a sheet for use. This is usually done by drawing a glazier's diamond down inside and placing the split cylinder on a stone slab in a special kiln. The heat causes the glass to spread out, and this spreading is accelerated by the use of a wooden tool which brings the glass close to the stone slab. The sheet is then carried into the annealing chamber where it is gradually moved down through a funnel heated at one end and cold at the other, so that when the sheet emerges it is ready for use.

The making of crown glass is interesting, and the glass produced has special inherent qualities. After the gathering on the blower's pipe has assumed the proper shape and size, another workman attaches to the mass of glass a pointed iron rod called a pointel, pontil, or punty, which is taken by the blower, after the blow pipe has been detached, and the opening widened by softening and revolving in front of a furnace, until the mass assumes a circular shape about 4 feet in diameter, when it is detached from the pontil, leaving the well-known "bull's eye" mark, and allowed to cool and anneal as before described.

What are termed "defects" in sheet glass for windows are of the greatest service in antique glasses, and all can be produced at will. Bubbles, blisters, threads, all of which give quality to antiques, from white to colours, are the result of the process the raw material undergoes. Numerous inventions are being experimented with whereby the mechanical production may supersede the older method, but this only applies to cases where large quantities are required.

Throughout the process of glass blowing at each stage there are many details we must again pass over in order to arrive at coloured glass and from this proceeding to a stained-glass window.

The methods employed in the making of coloured glass are the same as those used for sheet glass, the colouring material being mixed with great care and melted in the glass pots together with the other ingredients.

A mere statement of the oxides with which silica forms coloured oxides will be sufficient.

Iron has two oxides, the protoxide, colouring glass green, the peroxide, yellow.

Copper, again, has two oxides, one of which produces green and the other red.

Silver is never mixed with glass materials and fused with them because it does not readily unite with oxygen, and when it does so it loses its oxygen again at a high temperature. The high temperature necessary for the making of glass would reduce the oxide of silver to a metallic or black state. Silver is used for coating the surface of glass, the temperature of the muffle kiln, in which stained glass is fired, being so low that a beautiful yellow colour is the result.

Gold has similar tendencies, but can be utilised more effectively than silver, having a useful function to perform in the making of flashed ruby glass and gold pink.

Cadmium in the form of sulphides of cadmium produces rich yellow colour.

Chromium with iron makes blue, and with copper, green.

Aluminium is used for opal glass, opalescence being obtained by using arsenic and tin.

Oxide of cobalt makes an intensely blue colour.

Manganese dioxide gives a range of colour from purple to violet.

You will see, therefore, that the range is unlimited, the

Digitized by Google

various materials being used in conjunction with one another where possible to produce the colour required. For a long time, as the demand for better glass continued, all so-called defects were eliminated, with the result that stained-glass windows had to be composed of flat red and blue, until glass-makers were induced to reproduce the qualities of ancient glass with all the added knowledge of chemistry and modern methods.

As a modern chemist has said:—"It is probably not too much to claim that the modern workers in coloured glass have materials at their disposal which are at least as suitable for the purpose as those that were available in the best days of the ancient art."

Texture can be given in several ways, and by manipulation a sheet may have varying thickness and may even have other things introduced if need be. All this, however, can only take place during the process of making when molten, and I would warn you against believing a story I myself was told by a celebrated painter who was describing the methods of an equally celebrated glass-stainer.

This stained-glass man was depicted sitting in his studio working with glass, introducing here and there, where heavy colour was required, great lumps of stuff, thus enriching the quality of his work. I would remind you that the temperature of a glass-melting furnace is about 1,600° C. or 2,900° F., and that glass cannot be handled like clay, so I fear this tale is somewhat apocryphal and not to be credited.

The most interesting property of glass, and the one that concerns us most, is its transparency, for, with a few exceptions, its employment is due to its capability of transmitting light.

There are in use in laboratories very delicate instruments for showing that even the best and purest glass, owing to its absorption of light, cannot be said to be perfectly transparent, and when we remember that light is turned back by reflection at the surface of entry and again by reflection at the surface of exit from the glass, it is not difficult to realise that the transmitted beam is correspondingly weakened.

This partial transparency, however, introduces the scientific difficulty of light waves, and when we go beyond the range of ordinary visual light impressions of colour altogether change, and we can therefore dismiss the matter as being beyond the present scope.

The durability of glass under the action of the atmosphere or light has been carefully investigated and the chemical stability of glass surface put to severe tests. Glasses have been classified into groups according to chemical tests in laboratories, but it has been found in practice that certain so-called unstable kinds have given very satisfactory results. This is due to the fact that experiments where small quantities are used always give exaggerated results.

Glass found in windows of old churches has undoubtedly undergone a change, due to exposure to the action of the air, moisture and light. Its surface has become rough and, in the case of so-called "whites," light has caused the glass containing manganese (itself used to prevent the impurities in sand from affecting the colour) to assume a purple or brown tinge.

The probable explanation of the roughness and dimness of glass surface is that glass, being a mechanical mixture of different silicates, some of the silica present becomes hydrated and so dissolved out.

The chief physical, or rather mechanical, properties of glass are strength and hardness, and we must disregard as beyond our sphere properties such as elasticity and thermal endurance, expansion and conductivity, also electrical properties, and proceed to the account of the making of a stained-glass window.

II.—*Stained Glass.*

Mr. Christopher Whall says:—

"The art of stained glass, though reaching to very high and great things, is in its methods and processes a simple or at least a very limited one. There are but few things to do, while at the same time the principles of it touch the whole field of art, and it is impossible to treat of it without discussing these great matters and the laws which guide decorative art generally."

In the making of a stained-glass window there are six main stages: coloured design, cartoon, cutline, before painting, after painting, and leading, each stage having important sub-divisions.

The cartoon has to be drawn full-size from the scale design with all lead lines shown. From it, the cutline is next made by tracing on paper the centre of lead lines, to which the glass is cut. Each piece of glass as it is cut is attached to a large plate of glass with beeswax, and in this way an idea of the colour is obtained. The greatest care must be taken here to ensure the success of the colour-scheme, and several pieces may have to be cut for the one place before the right effect is obtained. The glass is then knocked off and entrusted to the glass painter, who proceeds to trace the outlines, from the cartoon, on to the glass, with an opaque brown pigment.

The pieces are then fired, which causes the colour to impregnate the glass and thus become incorporated with it.

The muffle kiln, in which the glass is fired, consists of an iron box with sliding shelves enclosed in an oven of brick work. The shelves are covered with powdered chalk, upon which the pieces of glass are laid, painted side up. The fire is underneath and the flames surround the box. After about seven or eight hours of burning at 1,300° F., the fire is drawn, and the glass allowed to cool gradually.

After firing, portions of the window are stuck up with beeswax on a glass easel, blackened to represent the lead lines, and the painter proceeds to translate or interpret the cartoon, by painting in two ways—matting and stippling the surface of each piece of glass with another specially prepared oxide of iron pigment.

The painter of a stained-glass window must be an expert draughtsman, and, as has been said, "is, in fact, to the designer what the pianist or violinist is to the composer of the sonata."

The portions are then taken off the easel and fired again, after which the painter works up, remodels, and finishes the painting of the whole window. The glass is fired for the third and last time, the silver for yellow stain where required being added on the back of the glass. The window is now ready for the lead worker, who builds all the pieces together with lead, soldering the joints, and generally completing the window.

Such is a brief outline of the processes, and instead of elaborating it, I am going to invite you to come and see a window actually in course of construction. In this way you will be able to acquire far more information than if you listened to a more detailed description minus the materials involved.

May I be allowed to conclude my account of the processes undergone and the methods employed in the making of a stained-glass window with a word regarding the detail of the stone or wood of the mullion and sash made for the reception of the window? Too little space is often allowed for the outside glass, the leaded work, and the iron saddle-bars, for when outside glass is used it goes into the groove, the leaded glass being glazed daylight size and the saddle bars fixed inside. The face of inside of stone jamb or wooden frame should never be less than 2⅜ inches; outside glass, stained glass, and bars take up ⅜ inch each, ⅝ inch outside and inside being left clear.

As Mr. Holiday points out in his book "Stained Glass as an Art":—

"Stained glass is strictly a technical art. The glazing of the open window space and the subduing of the light are purely practical matters, and the artist, having to deal with pieces of coloured glass, has to consider how these can be treated so as to be beautiful to the eye and interesting to the intelligence. The sole object is to glaze an aperture in the wall of a building for the purpose of admitting light and excluding weather. The glass, lead, and iron are primarily means to the end, and the question whether they shall be so treated as to constitute a work of art is a secondary one.

"A simple desire for beauty might sufficiently account for the introduction of artistic forms and colour into glazed windows, but practical considerations may have led to the same result."

Taine, in his "Philosophy of Art," writes of the Middle Ages as follows:—

"If one considers the stained-glass windows, or the images in the cathedrals, or the rude paintings, it appears as if the human race had become degenerate, and its blood had been impoverished; pale saints, distorted martyrs, virgins with flat chests, feet too long, and bony hands, hermits withered and unsubstantial, Christs that look like crushed and bleeding earthworms, processions of figures that are wan and stiffened and sad, upon whom are stamped all the deformities of misery and all the shrinking timidity of the oppressed."

Another writer sees the survival of the great classical tradition, "both in type of features and treatment of drapery, but nature becomes more and more deserted, symbolism more and more predominant, till at length the human form is totally misconceived, the drapery becomes a convention which has no connection with the limbs or body

Digitized by Google

it covers, even the eye and nose begin to present difficulties which can only be faced by a more or less symbolic rendering."

With the Renaissance came Donatello, Leonardo da Vinci, Michel Angelo, the Della Robbia family, all working from models and arranging their drapery as they desired, thus setting for us the standard of what drawing should be. In the series of slides I want to show the development from the crude statement to the elaborate working out of a definite conception capable of satisfying the eye by its beauty and the head by its soundness.

RIVER POLLUTION.

A DISCUSSION on River Pollution, its ethics, æsthetics and hygiene, formed the business of a sessional meeting of the Royal Sanitary Institute on April 7. Sir Francis Sharp Powell, Bart., M.P., vice-president, occupied the chair.

Mr. W. D. Scott-Moncrieff in opening the discussion offered the following propositions:—First, that river pollution was originally compulsory and forced upon our urban populations by legislation, and that the principal reasons for enforcing pollution were connected with questions of public health; second, that the Rivers Pollution Prevention Acts subsequently passed to prevent the pollution of rivers were also based upon regard for the public health, complicated with rights of property on rivers and canals; third, that a great deal of the legislation referred to was framed upon expectations and suppositions that have turned out, for the most part, illusory, and that many of the arguments used by the promoters of existing sanitary legislation are now proved to have been misleading; fourth, that the æsthetic element can now be shown to be the principal argument that is available as a justification for the enforcement of existing statutes; fifth, that in justice to the ratepayers of many of our great towns, the whole subject requires to be reconsidered in the light of more advanced knowledge based upon actual and dearly bought experience. Dealing with the first proposition, the speaker pointed out that previous to the passing of the first Public Health Act in 1848, there were practically no sewers in England at all, so that the pollution of rivers must have been upon a very limited scale, and would have remained so, in spite of the increase in population, if the construction and use of sewers had never been made compulsory by Acts of Parliament. The report of the Health of Towns Commission which appeared in 1844 revealed "such an astonishing amount of decomposing organic matter and filth of all kinds in the cities, that it aroused British sanitarians to a strong movement for the amelioration of these conditions, and led to the filth theory of disease."

The Town Improvement Clauses Act passed in 1847 gave local authorities powers to cause their sewers to empty themselves into the sea, or any public river; but the first Public Health Act which was passed in the following year, provided under section 145, that nothing in the Act was to be construed so as to authorise the local authority without previous consent in writing to use, injure or interfere with any water course or stream in which the owners of certain property, or the proprietors of canals or navigation might be interested. The difficulties encountered by local authorities at the time, said Mr. Moncrieff, must frequently have been in the nature of a dilemma, for when the General Board of Health was expiring in 1854, they found among their conclusions that "it was far less injurious to the public health to have the refuse of towns in water in the nearest river, than underneath or beneath dwellings." The next point to be considered was as to how far the public health was really implicated by river pollution, and if it could be shown to be a practically negligible quantity it followed that the whole of the legislation dealing with river pollution had been promoted and passed upon grounds that were illusory as regards the main argument, and, seeing that the law with regard to the proprietary rights had never been interfered with, all that was left, as a justification for the existence and enforcement of the Rivers Pollution Acts was, unless in exceptional cases, the plea of amenity. In other words, the æsthetic argument pure and simple was all that was left. Bearing directly on this question they had the evidence of Dr. Thresh, the medical officer of health for the county of Essex, given before the Royal Commission on Sewage Disposal in 1898. He then stated that, at the time he was associated with the Manchester and Salford Sanitary Association, he made an investigation as to one of the most squalid districts with a view to discovering some connection between the filthy condition of the river, which was "vile in the extreme," and the high death-rate. Taking the figures for ten years, "he could not find the slightest indication of any ill effect from the polluted river going through the borough." It might be said that the absence of any evidence to a contrary effect through the entire literature of the subject would be fairly conclusive when confirmed by the experience of Dr. Thresh in his evidence, but more than the investigation at Manchester was available in support of the contention that foul streams were not a danger to health, and this was to be found in the attitude of those who were experts in all matters connected with public health, not to mention the Local Government Board and the members of the Royal Commission on Sewage Disposal. At the Birmingham sewage works, sewage in excess of 15,000,000 gallons per day was being treated by a preliminary putrefactive process in tanks, followed by filtration, which was effected by means of nozzles expressly designed to break up the septic liquid into as fine particles as possible. The sewage was sprayed into the atmosphere without a precaution of any kind, even when high winds were blowing and distributing it through the air to distances which must approximate to that of salt spray carried by gales from the sea many miles inland. It followed that not only the local authorities and their officers, but also the Local Government Board and the Royal Commission on Sewage Disposal have cut themselves away from any possible relation between river pollution and the public health as an argument for the enforcement of the Rivers Pollution Acts, seeing that the sewage in question was far safer and much less expensive flowing between the banks of the Tame than being sprayed into the atmosphere, as it was at present. It appeared, therefore, that if the promoters of the Rivers Pollution Acts had been in possession of the knowledge that pollution had no bad effects upon the health of the public they must have abandoned their principal argument, and it was difficult to see what was left beyond questions of amenity. Of course, these remarks only applied to rivers not used for drinking, and there was no suggestion that the legislation referred to was carried out in anything but good faith. It was a different matter, however, with fresh legislation, and it was only fair that the ratepayers should be told what they were paying for before being subjected to fresh demands. There was no suggestion in what had been said that our rivers should not be purified. Many of them, such as the Thames, must be kept free from pollution at any cost, but the question of streams that were at present foul should not be treated as pressing on the ground of the public health in the face of the facts that were now in evidence. If it could be shown that the methods to be adopted were not likely to be superseded and were always certain to be successful, it would be a different matter, but it would be easy to show that that was far from being the case. The question was as to whether the ratepayers were ever likely to have a hearing at all. It should be remembered that in legislation of this kind it was quite easy to create vested interests that were naturally opposed to any interference with the volume of occupation, and that strong and influential bodies of opinion were brought into existence opposed to any modification of the law that might put a limit to the indefinite increase of fees and salaries. It should not be forgotten that while England had been making great efforts to solve the question of sewage disposal with small regard to the pockets of the ratepayers, many competent critics abroad were waiting to take advantage of our experience, and as an expert onlooker was often the best judge of a game, it might be well to quote from Dr. Calmette, the Director of Sewage Investigation in France, who said "that great land operations for the disposal of sewage can only be carried out by the principal capitals, or by the smaller communities where there are great tracts of land with sandy or chalky soils, very absorbent and of little value, and that, in the case of towns of less importance, and less favourably situated, it is absolutely impossible to have recourse to this method at all." Coming to bacterial processes as the latest phase in the solution of the sewage problem, although it was of comparatively recent date, it had been no exception to the rule of disappointed hopes and waste of money. So many points in connection with this branch of the subject were still in dispute, and there was such a complete absence of a scientific basis of any kind, that no statement, however guarded, was likely to meet with general acceptance. There were a good many people, however, who were agreed that contact beds had been associated with many disappointed hopes, and there were others who would think that that was putting the case very mildly. As to the question of hydrolysis as a preliminary to filtration, Mr. Moncrieff was of opinion that the process was altogether in its infancy, and was little understood, and as

Digitized by Google

for percolating filters he doubted if there were so many as ten existing installations in which the designers arranged for their construction upon even remotely satisfactory data. Taking the county of Stafford as an instance of special carefulness in the administration of the law, he had been informed that about 1,000,000*l.* had already been expended on sewage schemes, and he was not aware of any of that sum having been spent upon the preservation of rivers used for drinking. Supposing then that the æsthetic element was the principal feature in the way of a return for the money spent, it might be well to say something of other conditions prevailing in many of the districts that were traversed by filthy streams. The population of the pottery towns were not obsessed by any great regard for the beauty of their landscapes, and it was hard to see how they possibly could be. The same remark applied to the inhabitants of most, or at any rate many, midland towns. The river Aire as it flowed through what was once the beautiful estate of Esholt was filthy in the extreme, but even if it was as clear as crystal it would not save the landscape from being exceedingly depressing on account of the destruction of vegetation by the smoke from factory chimneys. It was no doubt most desirable for many reasons that the Aire and every other river should be unpolluted, but it was also only fair and reasonable that the people who had to find the money should know that it was amenity and not health that they were being called upon to pay for, and that, at any rate, they should no longer be called upon to conform to the letter of a statute which might be interpreted as meaning that nitric nitrogen in an effluent was excrementitious matter, and must not be allowed to pass into a stream. When an Act was in force containing a clause which there was no conceivable means of complying with, surely the sooner it was amended the better. By all means, said Mr. Moncrieff, let us leave no stone unturned to arrive at a final solution of the problems of sewage disposal and river pollution, but let us at least get it upon something approaching to a scientific basis before insisting upon ratepayers spending vast sums of money upon the purification of already filthy rivers on no more pressing ground than that of amenity.

Mr. Easton Devonshire said as a waterworks engineer and administrator he regarded the question of the pollution of rivers from a selfish standpoint. Mr. Scott-Moncrieff stated that his remarks on the Rivers Pollution Acts only applied to rivers not used for drinking purposes, and, further, that many of them, such as the Thames, must be kept free from pollution at any cost. He wished to know where would Mr. Moncrieff draw a line and under what conditions of expediency or public advantage he would keep some rivers pure at any cost while reserving others as sewage carriers for the financial benefit of isolated communities? They could not all obtain water from Wales, and therefore the question of the preservation of their rivers and streams should start from the axiom that all the natural surface-water courses of the country were potential sources of water supply. Advance in knowledge and practice might some day convince them that the æsthetically sound method of the wholesale disposal of sewage was not hygienically the most perfect. He was tempted to suggest that conclusion by the conditions which obtained in a continental town whose water supply he helped to administer—he referred to Antwerp. The municipal authorities there had recently published a tabulated statement, which showed the death-rate of Antwerp for last year was 12.7 per 1,000, a figure lower than that of any other city in Europe. The condition of sanitation at Antwerp was interesting. The town obtained its water supply from the River Nethe, an upper branch of the Scheldt. The intake of the waterworks was at a distance of about sixty miles from the sea, and there was a rise and fall of tide at the intake of about 10 feet. Four miles below, at the point where the Nethe gained the Scheldt, the sewage of Brussels was discharged by the River Senne and mixed with the volume of the main sewer. Two miles above was the town of Lierre, the surface drainage of which discharged into the river on the falling tide. Under such conditions great expense and continual care had been required in the purification of the water of the Nethe before it was supplied to Antwerp. Brussels, as they all knew, had geographical advantages which should make it extremely healthy, and it had, moreover, a system of sewerage which would satisfy the Public Health Acts in this country. Æsthetically the sanitation of Brussels was beyond criticism, and the conditions in which its population lived were in theory eminently hygienic. The population of Brussels was 400,000, and the death-rate last year was 15.7 per 1,000. Antwerp, on the other hand, had adhered to the old-fashioned and unæsthetic plan of every man to his own cesspit. There were no sewers, but the construction of the domestic cesspit was subject to strict regulations, and connection with surface drains was strictly forbidden. The population of Antwerp was 320,000, and it was built on a low-lying plain. The death-rate was 12.7 per 1,000, or three per 1,000 less than that of Brussels. It was true that before the water supply was generally used, when the inhabitants drew their drinking water from shallow wells generally built as a compartment of the cesspit structure, the sanitary condition of the city was not what it was at present, and it was interesting to note the correspondence between the diminution of the death-rate and the increase in the number of houses taking the water company supply. The system of sanitation in Antwerp he supposed could not be termed æsthetic, but hygienically the city stood at the top of the tree, and therefore it was with difficulty argued that the ethics of its sanitary methods were unsound.

Professor Bostock Hill agreed it was perfectly true that the pollution of rivers was caused primarily by sewers being led into them, but they might also add that it was due to the increase in population, so that it was not fair to attribute the faults of such a system to the Legislature. They were all aware that the general public had a very exaggerated idea of the emanations of pollution from streams. No doubt if a river ran smoothly it would be difficult to prove that diseases were produced by the pollution. They must, however, remember there was another point. Cattle drank from many of the sewage polluted streams, in some cases the only source of supply, and there was no doubt they often suffered bad health in consequence. The pollution of rivers might therefore be considered as affecting not only amenity, but the health of cattle and the lives of human beings also. Mr. Moncrieff had referred to the treatment of sewage by which particles were sprayed into the atmosphere. The speaker said he was the medical officer of health for Birmingham, and he had stated to the authorities that there was great danger to health in the exposure of considerable volumes of sewage. Attention had been called to the fact that most land schemes and chemical processes for the treatment of sewage were found to be at fault. That, however, was no reason why experiments should not be continued on lines which they hoped would ultimately lead to success.

Professor Henry Robinson said that twenty-five years ago he had suggested there should be a department of State to deal with the question of river pollution. Such a department would have kept all streams under proper control, supervising and regulating the use and abuse of them. There must necessarily have been experimental work in the past, and though many of the methods had not been successful, they had not yet reached finality. He urged authorities not to fall into the error of adopting one particular method as applicable to all places; that had been done to a large extent in the past, with the result that great sums of money had been wasted.

Mr. Midgley Taylor said Mr. Moncrieff's main contention appeared in his fourth proposition, which stated that the millions of money expended in this country on the improvement of rivers had been entirely wasted, excepting so far as the amenities of the rivers were concerned. He could not accept that proposition in any shape or form. He agreed that it was an extremely cheap and easy method to dispose of sewage by discharging it into a river, but some consideration had to be shown to towns situated on the lower banks of the watershed. It was allowable to disperse a small amount of sewage into a stream, but harmful to discharge such volumes of matter as to render it dead. Personally he entirely disagreed with the attack made on the Local Government Board, because he thought they were wise when they insisted that every local authority should possess an area of land available for the bacterial treatment of sewage.

Mr. J. D. Watson also upheld the view that they must consider each case on its own merits. Local conditions had to be taken into account and they almost all differed. Birmingham and its distributor had been referred to. The results of the methods adopted there proved the treatment to be a cheap one, and if they could take the town of Salford as a precedent there was no risk to the health of the community by spraying distributors.

Mr. H. P. Boulnois said Mr. Moncrieff had entirely omitted consideration of the pollution of rivers by factories. Although they had been making only experiments in England, they had something to show for their efforts, since he believed they had the best sanitation in the world.

Mr. H. D. Searles-Wood formally proposed a vote of thanks to Mr. Scott-Moncrieff, which was carried by acclamation.

OUR CONTEMPORARIES FROM OVER-SEAS.

THE *American Architect* has for the subject of its principal illustrations the new "Lotus Club," of which Mr. Donn Barber is the architect. The building is one of six storeys above the street level, and is somewhat unusual in composition from the importance of treatment given to the topmost storey. Some nice detail is illustrated, based upon Italian Renaissance work, but distinctly flavoured with a modern Parisian feeling. Another of the principal plates is devoted to the interior of Colchester Town Hall, by Mr. John Belcher, A.R.A. A short article on colour as applied to the exterior of buildings scarcely sufficiently deals with the subject, and the illustrations accompanying it are from seventeenth century German work; but as they are in black and white they do not help very much in the study of colour.

The Architectural Record (New York) has an article apparently intended for non-professional readers on "How to get a well-designed House," the examples illustrating the article being residences of Mr. Nicholas F. Palmer, Mr. Francis F. Palmer and Mr. George Palmer. They are given as examples of the failure that is likely to result when an employer goes to a decorating company, and show how easy it is for wealthy clients to spend plenty of money, and yet not get a well-designed house. A study of the New York suburb, New Rochelle, is largely another example of what to avoid. "A Contemporary Westover" is a good example of a modern adaptation of an old design, being admittedly, and in accordance with the instructions of his client, Mr. Charles A. Platt's reincarnation of the colonial house known as "Westover." The series of articles on "The Architect in History" is continued, and deals further with the architects of the Roman Empire.

The Engineering Record (New York) has an article on "Progress on the Bridge Loop Subway of the Rapid Transit Railway, New York," which is chiefly interesting from the illustrations and descriptions of the difficult and extensive underpinning of existing buildings that had to be undertaken. Two papers are reported on cast reinforced concrete piles, the one by Messrs. Sanford E. Thompson and Benjamin Fox, the other by Mr. M. M. Cannon. An article on cantilever and raft foundations for a twelve-storey building describes what seems to us a rather daring piece of reinforced concrete construction; the foundations of the internal columns of a twelve storey building of the total height of 150 feet being carried on cantilevers from the external steel framework.

La Construction Moderne illustrates the farm buildings erected at Bois-clair (Charente), designed by M. Henri Seay, architect, for the special requirements of a farm chiefly devoted to viticulture.

NOTABILIA.

THE *Illuminating Engineer* contains abstracts of papers by the editor, Mr. Leon Gaster, forming the second and third of his series of Cantor lectures delivered before the Royal Society of Arts on "Modern Methods of Illumination." In these lectures are treated the subjects of gas lighting, lighting by candles, oil, acetylene, petrol, air-gas and alcohol, and they are thus useful to architects who have to design country houses.

Page's Weekly gives Mr. F. J. Cook's paper on "Foundry Tests of Pig Iron," read before the Lancashire branch of the British Foundrymen's Association, which includes some valuable information, not only on the subject of tests, but on the modifications and the resultant character of cast iron that follow variations in the minutiæ of casting.

COMPETITIONS.

THE following is the result of a limited competition for an extension to the Southern Hospital, Liverpool, which takes the form of a detached out-patients' department, estimated to cost 8,500*l.*:—1, Haigh & Thompson; 2, Briggs, Wolstenholme & Thornley, FF.R.I.B.A.; 3, Willink & Thicknesse, FF.R.I.B.A.

MESSRS. MACINTOSH & NEWMAN, architects, London, have been awarded first place in the competition organised by the London and South-Western Railway for a concert-hall at Eastleigh. The second place went to Messrs. Petter & Warren, of Southampton, and the third to Mr. J. B. Fulton. The assessor was Mr. F. G. Knight, F.R.I.B.A.

MR. W. BEDDOE REES, A.R.I.B.A., architect, Cardiff, has been awarded the premium of 5*l.* 5*s.* offered in a competition for a chapel proposed to be erected at Penclawdd, Wales, to accommodate 800 sittings. The cost will be between 3,000*l.* and 4,000*l.* Mr. A. Conder, F.R.I.B.A., acted as assessor.

Correspondence

[The Editor will not be responsible for the opinions expressed by Correspondents.]

The Manchester Education Committee and the Architectural Profession.

SIR,—The Manchester Corporation has for some years past maintained a drawing office in connection with the education committee, in which all designs for new school buildings and for alterations to existing buildings have been and are prepared. Thus architects practising in Manchester are excluded from this work, and in the case of alterations the original architect may see his work copied or reproduced without any acknowledgment by the committee.

Surely a Corporation is not justified in setting up a department to do the work of an established profession, unless it can show clearly that the public will be thereby better served.

The education committee has had ample time to prove that its architectural department either does or does not justify its existence. Can the committee point to any superiority either in planning or in architectural treatment? While, as to cost, if the committee will state the average cost per scholar of the new buildings and will make a full return of the cost of maintaining its drawing office, it is submitted that it would at once be clear that its method does not make for economy.

The Manchester Society of Architects recently sent a protest to the Lord Mayor with reference to the new secondary school about to be erected in Chorlton Street in accordance with the method indicated above, but without result. This new school was planned by the education committee as an extension to the existing schools, which were built a few years ago by well-known Manchester architects. These existing schools provide good accommodation for secondary education at an actual cost, including some deep and difficult foundations, of 43*l.* per scholar. In the design for the new schools the general detail is copied from the old school, and the estimated cost, as shown by the accepted tenders, and which may be substantially increased, so far is 53*l.* per head—an increase of about 25 per cent.

Architects have at least the right as ratepayers to demand the same reasonable efficiency and economy in the spending of their money as would be demanded of them in their practice.—Yours truly,

ARTHUR S. BREWIS,
Secretary of Manchester Society of Architects.

April 8, 1909.

GENERAL.

Messrs. Henry Adams & Son, of 60 Queen Victoria Street, E.C., have been appointed consulting engineers for the proposed bridge over the Wey at Guildford, for which the design of Messrs. Clemence & Moon, of Guildford, was accepted out of seventy-five sets submitted.

At the Leicester Galleries, Leicester Square, W., there will open next week an exhibition of a series of cabinet pictures entitled "The Changing Hours," by Mr. Arnesby Brown, A.R.A. There will also be shown a series of water-colour drawings of the Sussex Downs, by Ruth Dollman.

Mr. Andrew W. Bell, late burgh engineer for Dunfermline, has lodged a claim against the Town Council for 1,351*l.* 15*s.* in respect of work expressly excluded from his contract as burgh engineer, and in other offices, and constituting work of magnitude. The Council unanimously decided to repudiate the claim.

The Longton Town Council last week considered proposals for improving the town hall by enlarging the large assembly hall, which has frequently been found to be inadequate for the purposes for which it was required. It is now suggested to do away with the ante-rooms and incorporate them into the large hall. The estimated cost of the work is approximately 6,000*l.*

A Special Committee of the Salford Town Council which was appointed in 1907 to inquire into the desirability of establishing a works department has decided against the proposal, and their recommendation was adopted last week.

Mr. Leslie Roseveare, chief assistant engineer and surveyor to the Birmingham Corporation, has been appointed borough engineer of South Shields. The commencing salary is 400*l.* per annum, and there were 122 applicants.

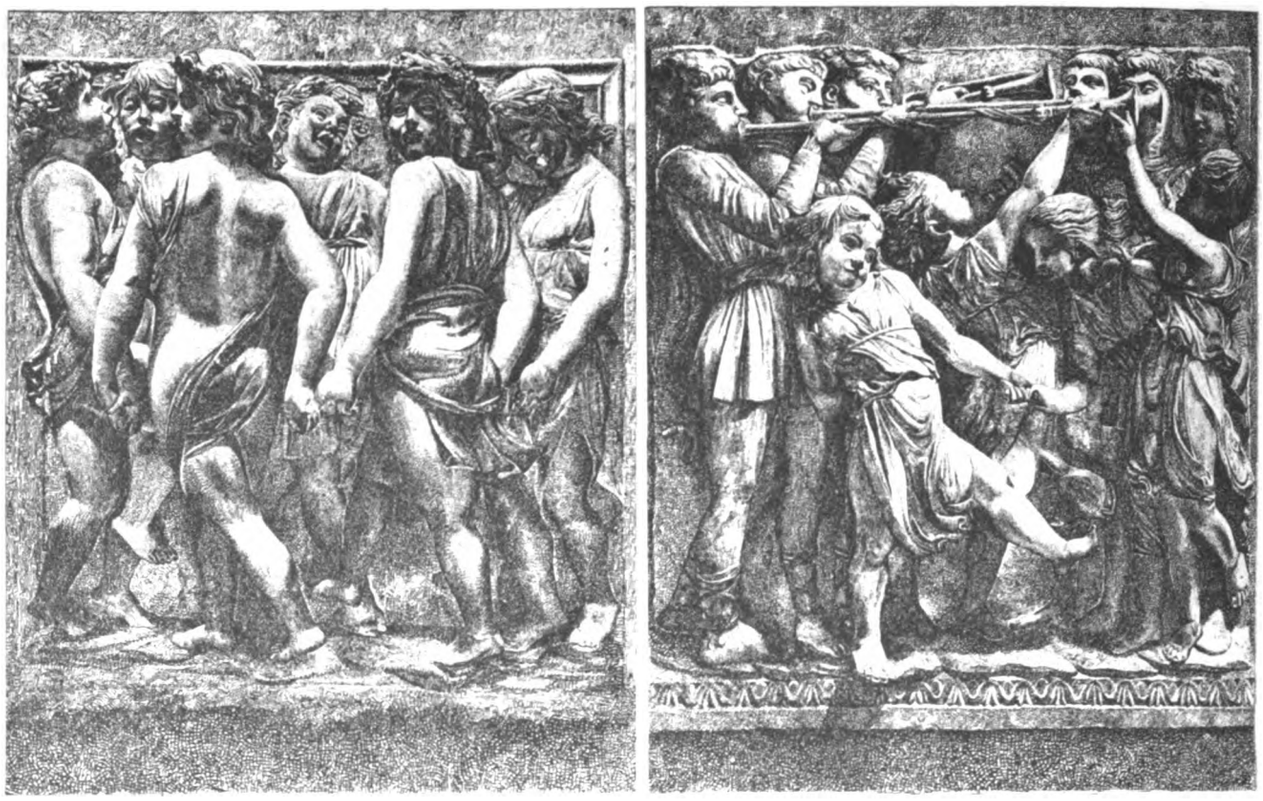
THE WEEK.

THE Council of the Surveyors' Institution has taken important steps towards the establishment of reciprocity between the various Governments and examining bodies of the Empire in the examination and qualification of land surveyors. In the Colonies land surveyors are not allowed to practise without passing qualifying examinations, and as these vary in severity and scope, a subject of the Empire proceeding from one part to another may find that he has to undergo a fresh examination before being granted a license to act as land surveyor. It is proposed to hold a Conference of the Surveyors-General of the Colonies at the Surveyors' Institution in London, in order to consider the scheme for reciprocity, and Lord CREWE, the Secretary of State, has invited the attendance of representatives of the various Colonies by a despatch to the Governments of Canada, Newfoundland, Australia, New South Wales, Victoria, Queensland, South Australia, Western Australia, Tasmania, New Zealand, Cape of Good Hope, Natal, Transvaal, and Orange River Colony. It is suggested as a basis for a reciprocal arrangement (*a*) That a candidate must have matriculated at some recognised University, or passed an equivalent examination; (*b*) that an examination in the theory of land surveying be then taken, the standard of this examination to be as high as that in force in South Africa; (*c*) that the candidate be then required to pass an examination in practical surveying, and that he be ineligible to sit for this final examination until he has had at least two years' experience with a practising surveyor. It is also suggested that each Colony, before granting a licence to practise, should be at liberty to require the passing of a further examination on the law and regulations relating to the survey, registration, and transfer of lands within the Colony. The reason for adopting the standard of South Africa is that there the qualification for a land surveyor is higher than in any other part of the Empire. We wonder if an Imperial qualification for land surveyors will some day be followed by an Imperial qualification for architects.

Now is the time when the British archæologist starts his digging for the season. The programme for Silchester has not yet been settled, but the excavation of the area within the walls of the Roman city having been completed last year, there remains the space between these and the lines of the older British encampment, and also the cemetery, the situation of which has yet to be discovered. The Roman fort at Elslack, between Skipton and Colne, is to be examined under the direction of a special committee, which includes representatives from the University of Leeds and the Yorkshire Archæological Society. At Avebury the site of the prehistoric temple will be further investigated by Mr. ST. GEORGE GRAY. The Liverpool Committee for Archæological Research in Wales joins forces with the Monmouthshire Society in work at Caerleon-upon-Usk, and with the Powisland Club at Caersws, in Montgomeryshire. Hadrian's Wall is to be further examined, and so also is the Roman fort at Newstead, near Melrose.

ARCHITECTS cannot always get their charges paid by public bodies, even if terms are agreed, and the Woolwich Union Guardians have been surcharged by the district auditor 143*l.* 16*s.* for fees paid to Messrs. DINWIDDY, who acted for the Guardians as surveyors and valuers for the purpose of the 1905 quinquennial valuation. The South Metropolitan Gas Company appealed to the Courts against the valuation, and lost. Messrs. DINWIDDY's bill of costs amounted to 997*l.* 18*s.* 6*d.*, which, on taxation, was reduced to 151*l.* 17*s.* 6*d.* This amount the company paid, and the Guardians paid the balance. Then the gas company, as ratepayers, opposed the passing of the accounts in which this payment by the Guardians was included, and the auditor, as we have said, surcharged.



THE exhibition of drawings now on view at the Fishmongers' Hall is a highly interesting justification of the methods adopted by the founder and art director of the Royal Drawing Society, Mr. T. R. ABLETT, for teaching children to draw. The great object of these methods seems to be the preservation of the naïve observation and spontaneity of expression that are characteristic of children's untaught efforts at drawing, but are too often crushed out by the usual formal instruction in so-called "freehand" and "model" drawing. The great principle of Mr. ABLETT's system is that the drawings are made not from copies or from actual objects, but from memory. Hence the youthful artist records only what he sees, and naturally, therefore, selects the salient points, the vital elements of his subject. The result of this is that in the work of children of about fifteen years of age we find drawing that most forcibly reminds us of Japanese work in its truth of selection and simplicity of expression. The value of this is seen, not only in the charming records of the life and motion of things, but in its bearing on decorative design, for which the power to seize and express the vital elements of form and colour is of primary importance. Hence there are many designs in the exhibition, the production of young students of between sixteen and eighteen years of age, that have an actual commercial value. The fact that H.R.H. Princess LOUISE, Duchess of Argyll, Sir CHARLES HOLROYD, and Sir JAMES LINTON give prizes, and themselves select the deserving recipients, is evidence that the work of the Royal Drawing Society has met with approval from creditable judges.

CURIOSITIES of archæological and historical value, found by workmen during building operations, often do not come within the ken of the employer or his architect, but are bartered away at less even than their intrinsic value for the traditional "pot o' beer." The London County Council has, therefore, done wisely by posting the following notice on the site of the new County Hall:—"If any workman comes across any out-of-the-way object or substance embedded in the soil in which he is working he is required to hand over the same to the foreman or the clerk of the works. Any find which is of geological or archæological value may prove to be the property of the London County Council, and a reward of an amount equal to the real value of the article, less about 10 per cent. for expenses, will be given to the finder, and will be paid out on application to the Clerk of the Council." It is well for London that we have an antiquarian, in the person of Mr. GOMME, as Clerk of the Council.

BOURNEMOUTH is once more starting a big building on paper. The pavilion, kursaal or casino is this time designed for the site of the Belle Vue Hotel, and is estimated to cost 70,000*l.*, according to the plans prepared by the Borough Architect. It has been resolved by the Town Council to adopt the scheme, but that by no means implies that it will be carried into execution. The Mayor argued in proposing the adoption of the scheme that Bournemouth with this pavilion would be the premier seaside town in the country, but there is a little place called Blackpool in the north countree which will, even when and if this great effort of Bournemouth's is consummated, still maintain a position as an attractive and pleasure-providing town that will yet remain enviable. Bournemouth is getting rather ridiculous in the matter of unrealised schemes, and we shall believe in this casino when we see it.

THE recent failure of a reinforced concrete reservoir at Annapolis, U.S.A., illustrates once again the high importance of careful workmanship in reinforced concrete work. The soil in which the reservoir is being formed is a fine sandy red clay, which, though rather impervious and capable of standing in a bank for a year or more if undisturbed, becomes a soft, sticky mud under foot traffic when wet. The concrete used was found, on investigation, to be good and in accordance with the specification, but, in placing it in position, the labourers had managed to get it mixed with the muddy clay bottom; hence the foundations of the piers were partly mud and partly concrete, and in some places the reinforcement had no bond whatever with the concrete.

RELIEFS IN MARBLE BY LUCA DELLA ROBBIA.

THE ARCHITECTURAL WORK OF THE LONDON COUNTY COUNCIL.

IT must have been patent to every one of the audience who listened to Mr. RILEY'S paper at the Royal Institute of British Architects on Monday last, that no one man, even with the energy and individuality of the late GEORGE EDMUND STREET, could have initiated, far less produced, all the designs of the buildings illustrated if he were hampered and harassed as Mr. RILEY must necessarily have been by the multifarious duties and responsibilities that belong to the office of the superintending architect of the London County Council. The duties that fall upon the holder of this office in respect of the administration of the London Building Acts alone are quite sufficient for any ordinary man to adequately fulfil. And when we remember that the buildings illustrated last Monday are only a small proportion of those erected under Mr. RILEY'S superintendence, we must feel more than ever convinced that he alone could not have designed them all from start to finish.

Although but few speakers followed the lecturer, it could not escape their notice, as it could not escape the notice of anyone who understands architecture, that the quality of design shown in the buildings produced by the London County Council during Mr. RILEY'S *régime* is of a very remarkable character, a character that marks an epoch in the history of English architecture, a character that could not have appeared at any time previous to the twentieth century or under other conditions than exist in the architect's department of the London County Council.

It is perfectly clear that this character of the recent architectural work of the Council is due to the initiative, the *naïveté* of young men—and clever young men. Of young men too in a subordinate and irresponsible position, whose originality has never been fettered by any fear of unfavourable criticism that might affect them personally, for their names are unknown outside the office except to a few. Therefore they have let themselves go, knowing that they would have no censor but "the chief," and have produced designs that would probably never have been ventured by these same young men if they had been in independent practice, and certainly not if they had been required to submit designs in open competition. To take, for example, one of the buildings not illustrated by Mr. RILEY, the fire station in the Euston Road, opposite St. Pancras Church, would any young man have ventured to send in such a design in open competition; and if he had ventured, would he have stood the smallest chance of success? And yet the modern architecture of London would have been the poorer if this design had not been carried into execution.

We have said that the character of the modern architectural work of the London County Council could not have appeared at any time previous to the present century. It is only within the last few years that there has developed amongst the younger men of the architectural profession the ability that is now evident, an ability that has seized upon the best side of the "new art" movement and refused to be bound strictly in the trammels of historic precedent. Nor would this ability have been seen if these young men had not been working under a "chief" who could distinguish between originality and eccentricity. It is clear that Mr. RILEY has had the power to select for his staff young men of ability, and whilst giving them scope for that ability has known how to restrain mere extravagancies of fancy. We can well understand that few designs have received the approval of "the chief" without modification and pruning down, but this has been so moderate and judicious that the verve of the original ideas has been preserved. Indeed, if we were inclined to be censorious, we should say that Mr. RILEY has been almost too indulgent to some of the crudities that mark the efforts of the young men, and at which we may be inclined to smile. But to have thrown cold water upon all of these would have been to sacrifice the essential character of the County Council architecture of the last decade. It would be easy, for example, to be severe upon the design of the Central Technical School and Training College, but we should rather recognise that the power and dignity of that design might easily have been lost by the exercise of such severity.

Mr. RILEY gave much attention in his paper to what we may call the financial aspect of the housing problem with which he has had to deal, and left the more purely architectural side of the question to speak for itself, but where before has the art of architecture been so manifest in the design of model dwellings and workmen's cottages as

Digitized by Google

in the works that he has directed? Plenty of other people have tried to make workmen's cottages examples of architecture, and have merely succeeded in making them pretty. Mr. Riley and his staff have made them dignified and beautiful.

We think that Mr. Riley did not do himself justice as the director of the County Council's architectural work, and we should have liked to have seen illustrated more of the really charming buildings that he has produced, but if he had nothing more to show than the Cannon Street fire station and the delightful little building that accentuates the ugliness of Hungerford Bridge, these would suffice to prove the high quality of the recent architectural work of the London County Council.

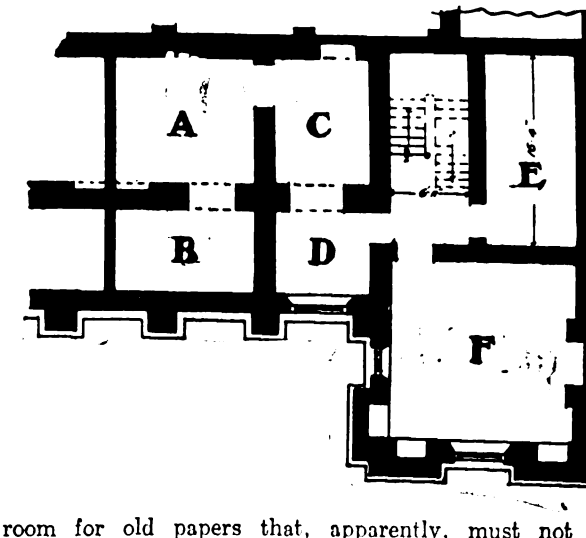
THE BUILDING EXHIBITION.

THE dominant characteristic of the present exhibition is that there is in it no predominant feature, but that it represents the activity of the building trade as a whole and in all its branches. On previous occasions there has frequently been impressed on the visiting architect that some one trade or department of building has monopolised an undue amount of space. In the present exhibition there is something of everything and not too much of anything. This result has been obtained from a levelling up, on the one hand, of trades that were in the past insufficiently represented and a pruning down of those that were formerly too exuberant.

Another characteristic of this year's show is that exhibitors have begun to grasp the fact that if they wish to attract the attention of visitors they must make their stands attractive, and that architects at any rate are not likely to be attracted by loud screaming and bizarre display. Whilst therefore there has been a notable increase of what, in its way, we may call artistic window-dressing, there is a marked decrease of the vulgarity into which the bid for prominence often leads exhibitors.

One great object of these exhibitions is to give manufacturers and merchants an opportunity of displaying and architects and builders an opportunity of inspecting novelties. Striking or epoch-making novelties are few to seek on the present occasion, but improvements and advances are to be found in practically every trade. Even in such an old-established and, one might expect, old-fashioned department as timber supply, there are novelties —and quite charming ones. Reinforcement is to-day a word of potent import in building, and in this direction also there are displayed novelties, and, what are quite as valuable to many of us as absolute novelties, things that have been more or less on the market for some time but have not been hitherto brought prominently before the notice of architects and builders.

It is an open question in the arrangement of a building exhibition whether it is advisable to group together all the exhibits of a particular trade or, as is done on the present occasion, to mix them indiscriminately. The former is preferred by the expert who wants to study the latest developments in one particular branch of building, the latter adds to the general attractiveness of an exhibition and, to our thinking, is more consonant with the general habit of mind of those for whom presumably these exhibitions are intended, architects and contractors. When this latter system is adopted a good classified index to the catalogue is a prime necessity, so that if a visitor wishes to see what is being done in some one department he can readily locate what he wants. This year the catalogue in this respect is a great improvement on some earlier ones, and though not quite perfect very fairly performs its function. We would suggest for the future two improvements; first, a plan in the catalogue of the exhibition showing where the various rows and numbers of stalls are located, and, second, greater prominence on the stalls of the numbers under which they are entered in the catalogue. Many architects keep their catalogues from one exhibition to another for reference, and when they see a stall that attracts them, desire to make notes in their catalogue. It is annoying in such a case not to be able to find a number on the stall, especially when the representative of the exhibitor is away at tea.



The display of competition designs for the poster to be used for advertising the exhibition is very interesting, and though, like all competitions, containing a number of attempts by vaulting ambition, includes several designs of high merit and not a few that must have run the successful competitor very close.

COMPETITION FOR NEW COUNTY OFFICES AT READING, BERKS.

WE gave last week some particulars relating to the conditions of this competition, for which about 250 architects have sent in their guineas.

There is a slight error in the plans originally sent out to competitors, but this has been corrected by an emendation that revises the line A F on Drawing No. 1, making the distance of the recess from A 11 feet 6 inches. A plan showing the position and depths of sewers has also been sent out by the County Surveyor. Most competitors will probably have noticed that the line A-A on ground-floor plan (Drawing No. 2) is wrongly lettered, and that the "sectional elevation on A-A" is looking north. The section, on this, of the wall of the hall of the Assize Courts is shown to apex of gable, and the springing of this gable is about 10 feet lower.

The "rooms in Assize Court buildings available for offices" are at present, on the ground, first, and second floors, used as such for the county offices located in the existing old houses, Nos. 28 and 30 Forbury, and, as competitors will gather from the plans, are well-lighted and useful rooms for their size. The staircase to these rooms is a wooden one in fair repair, with a book-lift in the well running from the basement to the top floor. For explanation of the basement we give a copy of the plan. A and B are quite dark, and A is used as a lumber

room for old papers that, apparently, must not be destroyed, but are not worth keeping. C is empty and contains an old stone sink in the recess on south side. D is used for electricity supply meters and is fairly well lighted. These four rooms are covered with brick vaults. E is at present used as the County Treasurer's strong-room and has an iron door. F is partly lighted and has a plastered ceiling, apparently on wooden joists. The recess on west side contains an old kitchen range, but the room is not used now. These basement rooms seem to be dry, but have a fusty smell from want of use and ventilation.

The hall of the Assize Courts is well lighted from windows on the north side and from top lights, so that the three windows in the west end shown on first-floor plan (Drawing No. 2) are of comparatively small importance.

The explanation of the "all rights of light" referred to in the particulars is that the houses Nos. 26, 28 and 30 Forbury, have been bought by the County Council

Digitized by Google

from Mr. SUTTON with rights of light over Messrs. SUTTON'S premises. The cross-hatched buildings shown on plan at south end (Drawing No. 1) are low one-storey trial houses used in Messrs. SUTTON'S business, and will, presumably, be re-erected on their building-line, 14 feet from the south end of site. Messrs. SUTTON'S buildings, where figured 10 feet 6 inches from west side of site, are one-storey only, and about 12 feet from ground line to eaves, with slate roof of low pitch coming down to same, except for one small dormer about 10 feet wide. Where set back 13 feet 6 inches from site, Messrs. SUTTON'S building is about 16 feet 6 inches from ground to eaves. Messrs. SUTTON'S frontage to Forbury is in red and yellow brick, and may, we think, be safely ignored by competitors in determining the character of their design. The Assize Courts are in Bath stone, showing incipient decay; hence probably the stipulation that Portland stone is to be used in the new buildings.

As is shown on the sewer plan sent to competitors by the County Surveyor, the site faces on the other side of the Forbury large ornamental public gardens, so that the site is remarkably open to the north. The Forbury is a very quiet road and out of the bustle of Reading, except, of course, when the Assizes are being held.

The local building materials of Reading are red-brick and tile; even the stock bricks of the district are red, and good red facings are easily obtainable. Bracknell, from which the well-known T.L.B. bricks come, is only a few miles from Reading.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

A MEETING of the Institute of Architects was held on Monday evening last, at Conduit Street, W., Mr. Ernest George, president, in the chair.

Mr. ALEXANDER GRAHAM (hon. secretary) announced the decease of Charles Thomas Whitley, Associate, elected 1870; Horace Moger, Associate, elected 1903; and William Candler Reed, Associate, elected 1845, and the oldest member of the Institute.

Mr. E. W. RILEY read a paper illustrated by lantern views, entitled

The Architectural Work of the London County Council.

Mr. RILEY said that as there were at the London County Council thirteen main committees, divided again into thirty-five sub-committees, which dealt with constructional works, he could not adequately deal with all the ramifications of that part of the Council's operations in a short lecture. He proposed therefore to confine his remarks to structural works which might be grouped under the following heads:—Housing of the working classes, electricity buildings, special educational establishments, fire stations, bridges and street improvements. In dealing with the first part of the paper, housing of the working classes, Mr. Riley said it had been laid down that not less than 400 cubic feet of air space per person for adults should be provided in the Council's dwellings, 200 cubic feet per head being permitted for children under ten years of age, and that the number of persons should not work out at more than two to a room. Infants born in a tenement did not count till they attained five years of age. It had been stated before a magistrate that a certain tenant being in an insanitary area, upon whom an ejectment order had to be served, could not pay the rent asked by the Council. He had been paying 5*s.* 6*d.* per week, but would have had to pay 8*s.* 6*d.* per week for a tenement in the Council's dwellings suitable for the accommodation of his family. The point emphasised was that the family was paying 2*s.* 3¾*d.* for each 100 feet super under the old insanitary conditions, whereas the Council was in a position to rehouse them in a thoroughly sanitary manner without any charge on the rates at a little over 1*s.* 10½*d.* per 100 feet super. The two generally accepted forms of construction adopted in the planning of block dwellings were (1) self-contained tenements; (2) associated tenements. The first had its own independent scullery, water-closet and offices, and except where a common laundry was provided, its own washing arrangements. The second type shared with other tenements the sculleries for preparing food, sinks, water-closets, and wash-houses. Latterly the Council had invariably adopted the so-called "self-contained" plan. A good example approaching completion was the Bourne Estate and Union Buildings, which provided accommodation for 3,902 persons. The average area of the living room was 150 feet super, and that of the bedrooms 100 feet. The average cubic space in the living rooms was 1,275 feet, and in the bedrooms 850 feet. Gas on the slot system was laid on by arrangement with the Gas Company. The buildings were planned for the internal blocks to lie north and south, so as to obtain the maximum of sunlight in the living rooms, and each tenement had at least one room looking on a garden. The type of plan designed for these buildings was an improved "balcony plan," arranged so that the living rooms and the bedroom did not look on to any of the balconies, and had an unobstructed light. The buildings were five storeys high with a few attics, and were constructed of fire-resisting material with steel joists and concrete floors. All the sculleries and water closets were separated from the habitable rooms by ventilated lobbies. The type of plan of the buildings had since the completion of the first block been adopted by other authorities for working-class dwellings, amongst others by the Metropolitan Boroughs of Bermondsey and Hackney.

The Caledonian Estate was about two acres in extent, and being acquired by the Council under Part III. of the Housing Act there was consequently no rehousing obligation. The estate was therefore charged with the total capital expended in respect of land, buildings, gardens, &c., and all other outlay in connection with the development of the estate. After making due provision for all expenditure, including debt charges, the accounts showed a profit of 1.15 per cent. on the gross rental. The buildings were five-storey block dwellings containing 272 tenements, the four back blocks being of the improved balcony type. The front block had closed staircases with windows and white glazed tiled dado, giving approach at each landing to four tenements, averaging nine rooms for each set of four tenements. On the basis of two persons to the habitable room, six one-room tenements, 116 two-room, 146 three-room and four four-room tenements accommodate 1,384 persons. The estimated cost of the buildings and incidentals was 57,396*l.* 10*s.*, and worked out at 7.86*d.* per cubic foot. The most extensive developments under this part of the Act, however, had been the laying out of "Cottage" estates. Three large estates of this kind were in progress at the present time, while a fourth, the Old Oak Common Lane Estate, had been acquired, and a scheme for development was in progress. Totterdown Fields Estate at Tooting comprised 38¾ acres. The roads had all been formed and cottages had been erected on about 25½ acres. Norbury Estate comprised about 30 acres. The roads had been formed on about 18 acres, and cottages erected on about five acres. White Hart Lane Estate was divided into two parts. The larger or southern section comprised 178 acres; the roads had been formed on about 35½ acres and cottages erected on about 18.9 acres. The northern section comprised 46 acres and was not yet ripe for development. The Council had all along intended that this isolated portion should wait till the neighbourhood had opened up and become ready for building accommodation. Endeavour had been made to render the cottage estates successful, both from a commercial and architectural point of view. They were two-storey buildings arranged in short terraces with spaces at intervals, and they were almost invariably set back from the forecourt fence 5 to 14 feet. Each cottage had its own front door and its own plot of garden ground in rear. In every cottage suitable fittings were provided. The scheme for development and designs produced had been largely influenced by the following considerations:—(1) Economy of land area and road construction in proportion to buildings, but in no case had more than 33.33 cottages per acre been put on the land, the average number being about 29.14; (2) the avoidance, as far as practicable, of deep external back projections in close juxtaposition, which tended to cause insanitary pockets and prevent the free circulation of air currents along the backs of terraces of houses.

Mr. Riley said it might add interest to the paper if he referred in general terms to cost of construction and the methods employed of issuing particulars for tender and contract in regard to working-class dwellings, the expenditure on which had to be reduced to a minimum.

For large works plans were prepared in the usual manner, and specifications and bills of quantities were also prepared. Sometimes "open," sometimes "selected," tenders were invited. The cost of block dwellings, including professional and incidental charges, erected during the past five years, had worked out at about an average of 86*l.* per room, or 9.8*d.* per cubic foot. For cottages, however, it had been found generally most economical to obtain tenders as follows:—The working drawings of the buildings are prepared to ⅛-inch scale, and a few essential details to a larger scale. A simple specification is prepared giving very little detailed

Digitized by Google

description of construction, but specifying the quality of the articles required. To the specification are attached the Council's instructions for tender, form of contract, and schedule as to rates of wages and hours of labour. No bills of quantities are prepared, but each contractor invited to tender is supplied with a set of drawings, specification, form of contract, &c. Under this procedure there was no difficulty in getting excellent contractors, both in large and smaller ways of business, to compete. This simple means of obtaining competition worked admirably, not only in the initial process of obtaining tenders, but in the adjustment of variations, &c., for at every step the architect knew just how the cost of the work stood. Care had to be exercised in the granting of advances for work done, but there was no difficulty in framing a table of values on which to work.

The cost of cottages varied considerably according to district.

Cottages recently erected had cost:—

At Totterdown Fields Estate, Tooting:—Five-roomed cottages, including professional and incidental expenses, 349*l.* to 384*l.*; four-roomed cottages, including professional and incidental expenses, 235*l.* to 273*l.*; three-roomed cottages, including professional and incidental expenses, 192*l.* to 216*l.*—the average cost per cubic foot being 6.14*d.*

At White Hart Lane Estate, Tottenham:—Five-roomed cottages, including professional and incidental expenses, 253*l.* 16*s.*; four-roomed cottages, including professional and incidental expenses, 204*l.* 4*s.*; three-roomed cottages, including professional and incidental expenses, 168*l.* 16*s.*—the average cost per cubic foot being 4.97*d.*

The lecturer then described the buildings constructed in connection with the electrification of the whole of the tramway system within the County of London, which involved the large generating station at Greenwich and sub-stations placed at convenient positions near the tramway routes. The area of the Greenwich station was about 3.7 acres, with a frontage to the river of about 240 feet. The next division of the lecture related to educational establishments including technical institutes, among which were cited the Central School of Arts and Crafts and the London Day Training College in Southampton Row; the School of Engineering and Navigation at Poplar; the Westminster School of Art and Technical Institute; the School of Arts and Crafts at Hammersmith, and other technical schools at Shoreditch, Paddington and Brixton.

The Central School and College in Southampton Row cost approximately 115,000*l.* exclusive of equipment, the Naval Engineering School at Poplar 27,000*l.* exclusive of machinery, and the Westminster school and institute 21,000*l.*

The planning of fire brigade stations was described at some length, the two essential points in arrangement being the provision of adequate accommodation for the necessary apparatus and the housing of the men in such a way that they could at any time reach the positions assigned to them as quickly as possible to ensure a rapid turn-out.

Referring to the Holborn to Strand improvement scheme, Mr. Riley said the Council, in the earlier stages of the improvement, fully realised the necessity of obtaining the best results in the new streets which, while affording improved facilities for traffic, it was hoped would result in an architectural treatment of great dignity; it was held that, if a high standard of excellence were obtained, the cost of the improvement would be reduced. The Institute co-operated with the Council in selecting eight architects, who were invited to submit sketches for the various frontages. Those selected by the assessors as submitting designs which were considered suitable for adoption by prospective lessees were Mr. H. T. Hare, Mr. W. Flockhart, Mr. M. Macartney, and Mr. L. Stokes. However desirable in the interests of architecture the adoption of any of these schemes would have been, the Council had hesitated to impose upon its lessees any coherent scheme as suggested by these exponents, with the result that each design submitted for new buildings was considered on its own merits. The Council had become, by reason of the surplus land acquired in carrying out improvements, one of the largest landowners of London, with a rent roll of 325,000*l.* a year, and, having regard to the interests of the ratepayers, it was most desirous of avoiding any restrictions as to elevation, &c., which might delay the letting of land. The building conditions had been amended in such a way that rendered them less restrictive than those in operation on any other large London estate. Although the circumstances had not been so propitious as they might have been, the result as regarded the architectural treatment was decidedly above the average hitherto attained in other metropolitan improvements. If the general effect of the future buildings did not fall below the present standard, the result would be one for congratulation.

The Council, too, had instituted a means of preserving a suitable record of architectural and historical buildings demolished in connection with improvement schemes. Every building was carefully surveyed, and if desirable, suitable photographs taken; when any valuable detail, either in stone, wood or iron was found, a measured drawing was prepared. That had been the practice for some years, with the result that an interesting collection of many hundreds of drawings and photographs had been formed which would be of great value in illustrating for future generations a phase of old London which was rapidly disappearing.

In connection with street improvements, which formed a very important part of the work of the Council, Mr. Riley said attention was at once arrested by the fact that the actual or estimated gross cost of county improvements effected by the Council since 1889, excluding bridges, had amounted to 11,000,000*l.*, towards which the local authorities had in some cases contributed. That large sum could only be regarded as the cost of patching up mistakes and remedying deficiencies which should never have arisen had any attempt been made originally to lay out London on a definite plan. The recommendations of the Royal Commission on London Traffic as to street improvements commence by affirming that at the root of the problem of London locomotion was the fact that many of the streets were too narrow; that fact was always endorsed at academic discussions, and idyllic hopes for the future were expressed; but it was to be doubted whether anything was being done to prevent a recurrence of the evils of which the effect was now so apparent. From 1897 to 1907 about 143 miles of new streets were sanctioned by the Council and 81,870 new buildings were erected in the county; but that enormous development had not been influenced by any directing control, and the meagre powers exercised by the Council under Part II. of the London Building Act provided only for a minimum standard which was quite incompatible with that laid down by the Royal Commission as to the width necessary in new streets. The building owner being only human, and his professional adviser being naturally anxious to make the most of his client's property, it was not, perhaps, surprising that the ideals which were so earnestly advocated in theory were not found to be adopted in practice in the development of suburban London. The want of control could only have disastrous effects, perhaps in the near future, but despite the high conceptions of what ought to be, it was doubtful whether any proposal, such as an amendment of the London Building Act on the lines of the Liverpool Act of 1908, to require a width of 80 feet in new main streets, would be favourably received. The Town Planning Bill might have a beneficial effect, and the Bill as amended certainly gave greater promise by enabling land in course of development or which, although built on, was necessary to a scheme, to be dealt with in such schemes. The scope of the Bill in London would be restricted by reason of the comparatively small area within the county which was now unbuilt on, but the Bill would in any case prove a useful supplement to the Building Act by enabling the provision of arterial communications to be required.

In his concluding remarks Mr. Riley referred to Vauxhall Bridge, and the great difficulties which beset the work in its early stages. He alluded to the proposed erection of pylons upon the shore piers, and said that though the value and importance of the whole scheme would be materially improved if something of the kind were added, the probability of such completion was only problematical. He expressed, too, his appreciation of the not wholly successful efforts made by the Institute to preserve unimpaired the beauty of Waterloo bridge in the perforation of the abutment by the tramway near Lancaster Place.

Mr. J. T. TAYLOR, London County Council, in proposing a vote of thanks to the lecturer, said the architectural work of the London County Council might be considered as in two volumes. They had the first in Mr. Riley's paper, and there was the second volume, or sequel, in the educational buildings undertaken by Mr. Bailey, and he hoped the Council would have an opportunity of hearing it. Mr. Riley's position was a very difficult one, and the speaker said he wished on behalf of the London County Council to state how the members of that body appreciated his work. It would seem that necessarily the Council's architect must come into conflict with some of the architectural profession who might feel aggrieved that they were not given more opportunities. Mr. Riley had a dual position to fulfil in the interests of the London County Council, the numerous com-

Digitized by Google

mittees, and the chairmen of committees. He was sure it was not easy to meet the views of all and reconcile them with what was right. A good deal of the work brought before them in the lecture might be thought to be of an engineering character, but they would agree that in the architectural part of the design the work showed a breadth of treatment and a dignity of purpose which reminded them of some of the old Roman work, and on the whole the designs were extremely successful. The building on the Thames Embankment that had been shown to them was a typical example. It was still a vexed question as to how far the London County Council could do design work in architecture to the exclusion of the profession generally. He sympathised with architects, and in a large measure shared their views, because he felt that official architecture was apt to run into grooves and become stereotyped. The London County Council appreciated originality and variety in building, and it was their desire and aim to have the best possible results that could be obtained, and if better schemes were submitted by outside architects they would be ready to consider them with a view to co-operation, and he felt he carried Mr. Riley with him in that opinion. The lecture gave only a small idea of the work undertaken by the Council's superintending architect. He, the speaker, was in a position to see the magnitude of those duties, and he was often surprised that Mr. Riley was able to achieve as much as he did. He for one would like to see work of a special character thrown open to competition, or to selected outside architects, and he felt Mr. Riley would not be adverse to the proposal.

Mr. T. J. BAILEY seconded the vote of thanks, and said the multitudinous number of buildings which went through Mr. Riley's hands, and the variety of them showed perfectly clearly that the duties must entail a great strain on the architect's brain. He said he knew the difficulties which confronted an architect in dealing with various committees and the troubles which arose in working for a body like the London County Council, when different committees had their own business to carry through without official cognizance of the work done by other committees. Mr. Riley had kept his buildings within the limits of the economic restrictions imposed, but he did not know if Mr. Riley had often experienced the difficulty of treating with the finance committee.

Mr. J. W. SIMPSON said if he might be allowed, he would like to add an even more enthusiastic note to the vote of thanks than that of the proposer and seconder. He thought many of those present would have been struck with the great dignity and beauty of much of the design which had been shown on the screen during the lecture. They had had recently an interesting paper by Mr. Swales on "American Architecture," and he thought they could say, without hesitation, that the work they were considering that evening was quite equal to the large and fine conception of utilitarian architecture which Mr. Swales had brought to their notice.

Mr. W. WOODWARD wished to add his mead of praise to the expressions passed on Mr. Riley's paper, which he thought was terse and very much to the point. He asked whether it was desirable that the London County Council should erect dwellings for the working classes or whether such buildings should be left to that outside enterprise which was always forthcoming to meet a demand when profit was to be made? With regard to block dwellings he thought they would all agree that the Metropolitan Board of Works, followed by the London County Council, did most seriously anticipate unnecessarily the pulling down and clearance of sites before they were at all ready to erect buildings on those sites, causing hundreds of poor persons to be sent away without provision being made for rehousing them, or for the immediate starting of the housing schemes. That mischief had been remedied somewhat by the London County Council, but he wished to make some criticisms. The cost for maintenance, returnable as rent, was put at 8*s*. 6*d*. per week in the Council's tenements. Such a sum formed a very large proportion of the average wage earned by those for whom the dwellings were erected. It was about one-fourth of the wage earned, and therefore excessive, because he thought they would agree that one-eighth of the wage was the fair proportion that should be expended in mere rental. It seemed therefore that notwithstanding the cost per foot cube, some other means should be taken to provide dwellings for the real working classes who could not afford to pay more than 4*s*. 6*d*. or 3*s*. 6*d*. for a decent tenement. It devolved into a question as to whether the cubical area of the rooms might not be reduced, and more dwellings placed on the same site. It seemed also that the desire for two-roomed tenements was in the ascendant, and if they were to provide those dwellings the land must be obtained at far less cost than generally ruled. The profit on the Caledonian estate property had been mentioned, but Mr. Riley did not tell them what the profit would be on the net rental. Those buildings were not erected at an excessive price, but it seemed that, allowing for repairs and maintenance in the future, if the London County Council could only secure 1.15 per cent. now, that in the future there would be scarcely any profit. The cottage dwellings was a scheme which would meet with the commendation of everyone, and the speaker added humorously that if the building trade did not improve, he would expect to find many architects allocated to those cottages. He questioned, however, if the scheme could be a success financially, for with thirty-three cottages per acre, and 1,300 feet garden to each, it was obvious that the land must be purchased at a very small cost indeed. He could not account for the very great difference in cost between the cottages at Tooting and Tottenham. In alluding to the street improvements schemes, Mr. Woodward said the London County Council would do well to make the rents in the Holborn to Strand area still more progressive than they were.

Mr. RILEY, in his reply, agreed that land acquired for housing schemes had in the past been allowed to remain undeveloped, and one plot had been vacant for thirteen years. It was, however, he said, generally admitted that land ear-marked for housing purposes rendered certain sites in London valueless. The difference between the cost of the cottages built at Tooting and Tottenham was wholly topographical. At the latter place Fletton bricks were obtained easily, at Tooting they had to get Kent bricks, and they knew that if they got their bricks cheaply the financial problem was solved.

ARCHITECTURE: ITS TRUE PRINCIPLES.—VIII.

By R. OWEN ALLSOP.

SYMMETRY AND BALANCE.

IT is probably for the reason just suggested—the eye seeking a centre, as the mind sees a central motive—that we may best arrive at an understanding of the nature and true value of exact symmetry. Of itself symmetry signifies little; it is easily formed—most easily of all by a machine, as a turning lathe. It is offensive if forced, and yet can never be ignored without compensating effects of balance. The requirement of perfect unity of any material object necessitates a centre line or a point. The highest symmetry and the greatest unity are doubtless best exemplified in the sphere, but only perfectly so when it is poised in space. The value of symmetry is that it conduces to unity of effect. Thus we may plan a building by placing together, "anyhow," the several rooms, and in the same way we may make elevations wherein the several necessary solid features crop up anywhere and anyhow. Such a method of design necessitates little or no thought. Plainly, therefore, the designer who produces symmetry is so far superior to the other in that it had only been by an effort of reason and by persistent endeavours that he has been enabled to produce this symmetry. The *misapplication* of symmetry is when convenience and use of the building are sacrificed to the production of a symmetrical elevation.

Thus we call to mind a building with a very greatly extended "front," in which this chief façade is in perfect equal-sided symmetry. It would not be difficult to show that some (if not very many) practical conveniences must have been here sacrificed to obtain—what?—that which is produced in a few minutes by a turner, as when a wooden baluster is formed from the square timbers.

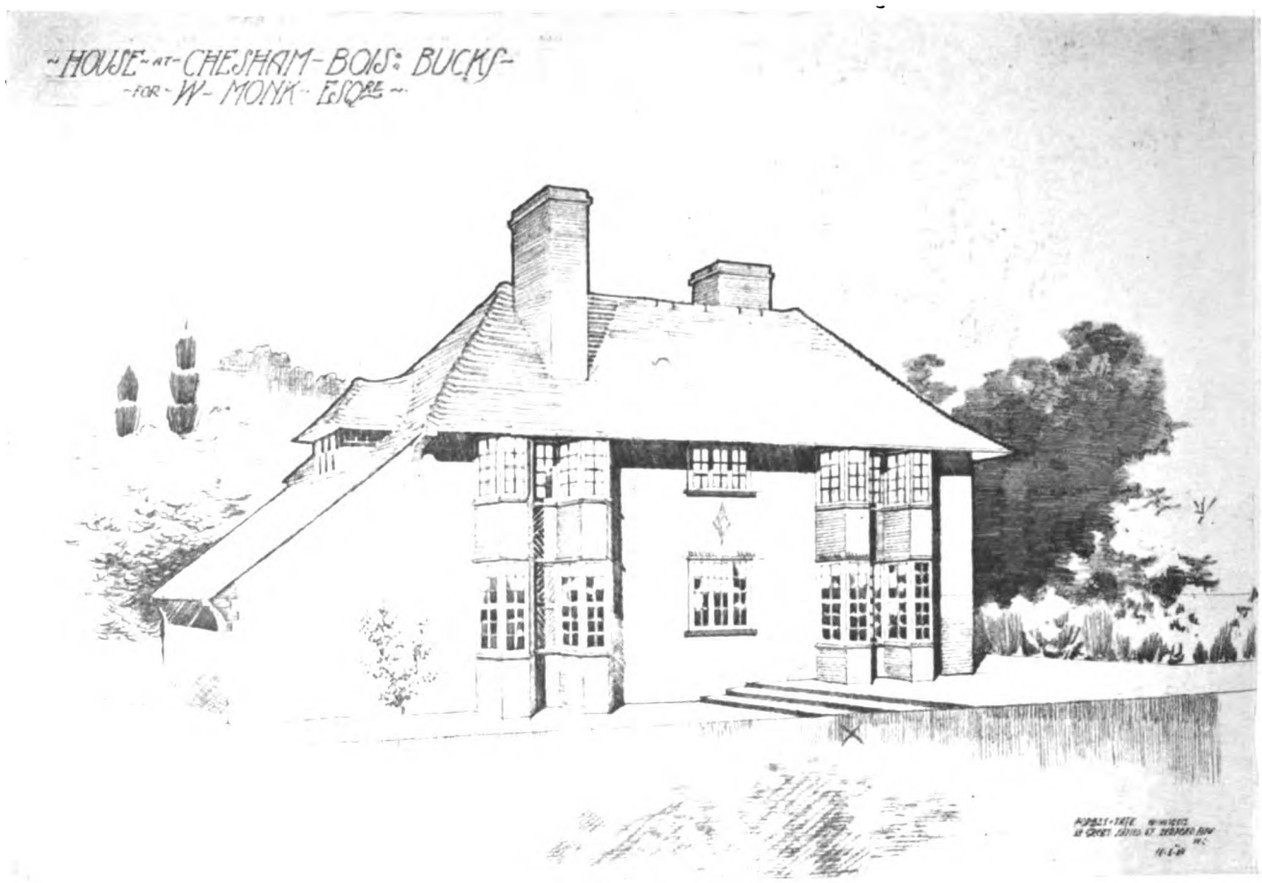
We might say that symmetry should be sought where practical needs do not interfere, and that generally there should be rigid bi-symmetry in the detail and perhaps in minor massing. We remember a design of a capital by ADAM in which one side there is a human figure and on the other side a horse's head, and scarcely anything has appeared to us more offensive.

The argument against symmetry in large parts is that however correct the symmetry may be in the geometrical representation, in actual fact we cannot see this genuine bi-symmetry. Many buildings are so large or so shaped that in execution the geometrical symmetry cannot anywhere be perceived by the eye.

Digitized by Google

Fig. 20.—SANTA SOPHIA, CONSTANTINOPLE.

A common argument, too, against symmetry is the evident fact that material objects, excepting certain crystals in small matters and the heavenly spheres in large, are not strictly bi-symmetrical. Most leaves are roughly symmetrical, but no close examination is required to show that the symmetry is imperfect—that is, that there is no mathematical reproduction of similar forms either side of some exactly central axis. To this it might be urged that inasmuch as the designer drawing his inspiration from nature does not copy one special form, but generalises, the spirit he perceives underlying most plant life is that of the truly symmetrical, but that to obtain variety there is a constant divergence from this. And in respect to flowers, the basic formation of most such is truly symmetrical, the curl and curve being for the sake of variety.



It seems possible that the sublimity of nature is an attribute of Divine creation that can have nothing germane to the creations of man. The apparent arrangement of the stars in the firmament is to be described as "anyhow." They appear to be the type of chance and haphazard. We know that, on the contrary, the arrangement is that of perfect order, only the finite mind not being able to comprehend infinity, we can express no opinion on the matter, our brain not having grasped the meaning of the whole conception any more than a fly on the cathedral window could comprehend the arrangement of the whole building. Possibly the same may be said respecting the universally persistent asymmetry of natural life on the earth. There is, in a profusion of naturally growing flowers, an echo of the same sublimity of arrangement that we see in the stars. From the considerations here made we may deduce a belief that there is no argument against symmetry in the fact that natural objects are seldom, if ever, perfectly so. The claim for equal-sided treatment must be based on some other grounds. It is not reasonable to look too much for inspiration respecting the arrangement of inorganic masses—as in architecture—to organic life, as plants. A more intelligible course would be to inquire into the arrangement of the lifeless matter subject to law and order, and here we find the crystal which is the production of what we call order out of the natural disorder, as we should say, a sublimity in terms—in matter—assumes symmetrical shapes having various phases of symmetry; and so, too, on the larger scale, the formation of suns and worlds out of primitive nebulous masses (the nebular hypothesis) results in symmetry of the sphere or spheroid, or at times a ring, as that of the planet Saturn. The truth is, possibly, the question of symmetry in design, especially as applicable to architecture, must be considered unsolvable. All that we see is that, not being able on our plane to produce true sublimity, we must in our weak human nature fall back upon rigid bi-symmetry as a symbol of order on a lower scale, and leave to natural forces—earthquakes, winds, frosts, rain, and time-weathering—the production of that "parasitical sublimity" discovered by Ruskin and most plainly evidenced in the ruin.

The old story of the complaint that a terrestrial and celestial globe did not constitute a "pair" seems often to find an echo in architectural design. It is just possible to imagine that some rigid equal-sided symmetrist would prefer the decorative inscriptions in Santa Sophia at Constantinople to be alike on opposite positions. The absurdity would be here apparent enough; but it is often just as inconsistent to create artificially equal-sided compositions in solid architectural device.

Exact symmetry, based on order, is evidently a true principle in architectural design; but the premises being thus made the whole grounds require examination. There is plainly a subtle relation between symmetry and asymmetry in architecture. It would appear that they are correlated much as regularity to irregularity, rough to smooth, or any other pure contrast where mutual enhancement is the outcome.

(To be continued.)

NOTES AND COMMENTS.

The British Fire Prevention Committee has issued a "red book" containing a detailed account of a test on an "armoured" door, being a sliding door of four thicknesses of deal and covered externally (*i.e.* armoured) with tinned steel plates. The object of the test was to try if such a door could obtain classification under the Committee's scheme as affording "full protection" (Class A). For this it would be necessary for the door to effectively resist a fire of two and a half hours' duration at a temperature gradually increasing to about 1800° Fahr., followed by the application of water for two minutes on the fire side. This proved too severe a test for such a class of door, as when the wood was burnt the door collapsed before the expiration of the time limit, and accordingly armoured doors should be regarded as affording temporary protection only against fire.

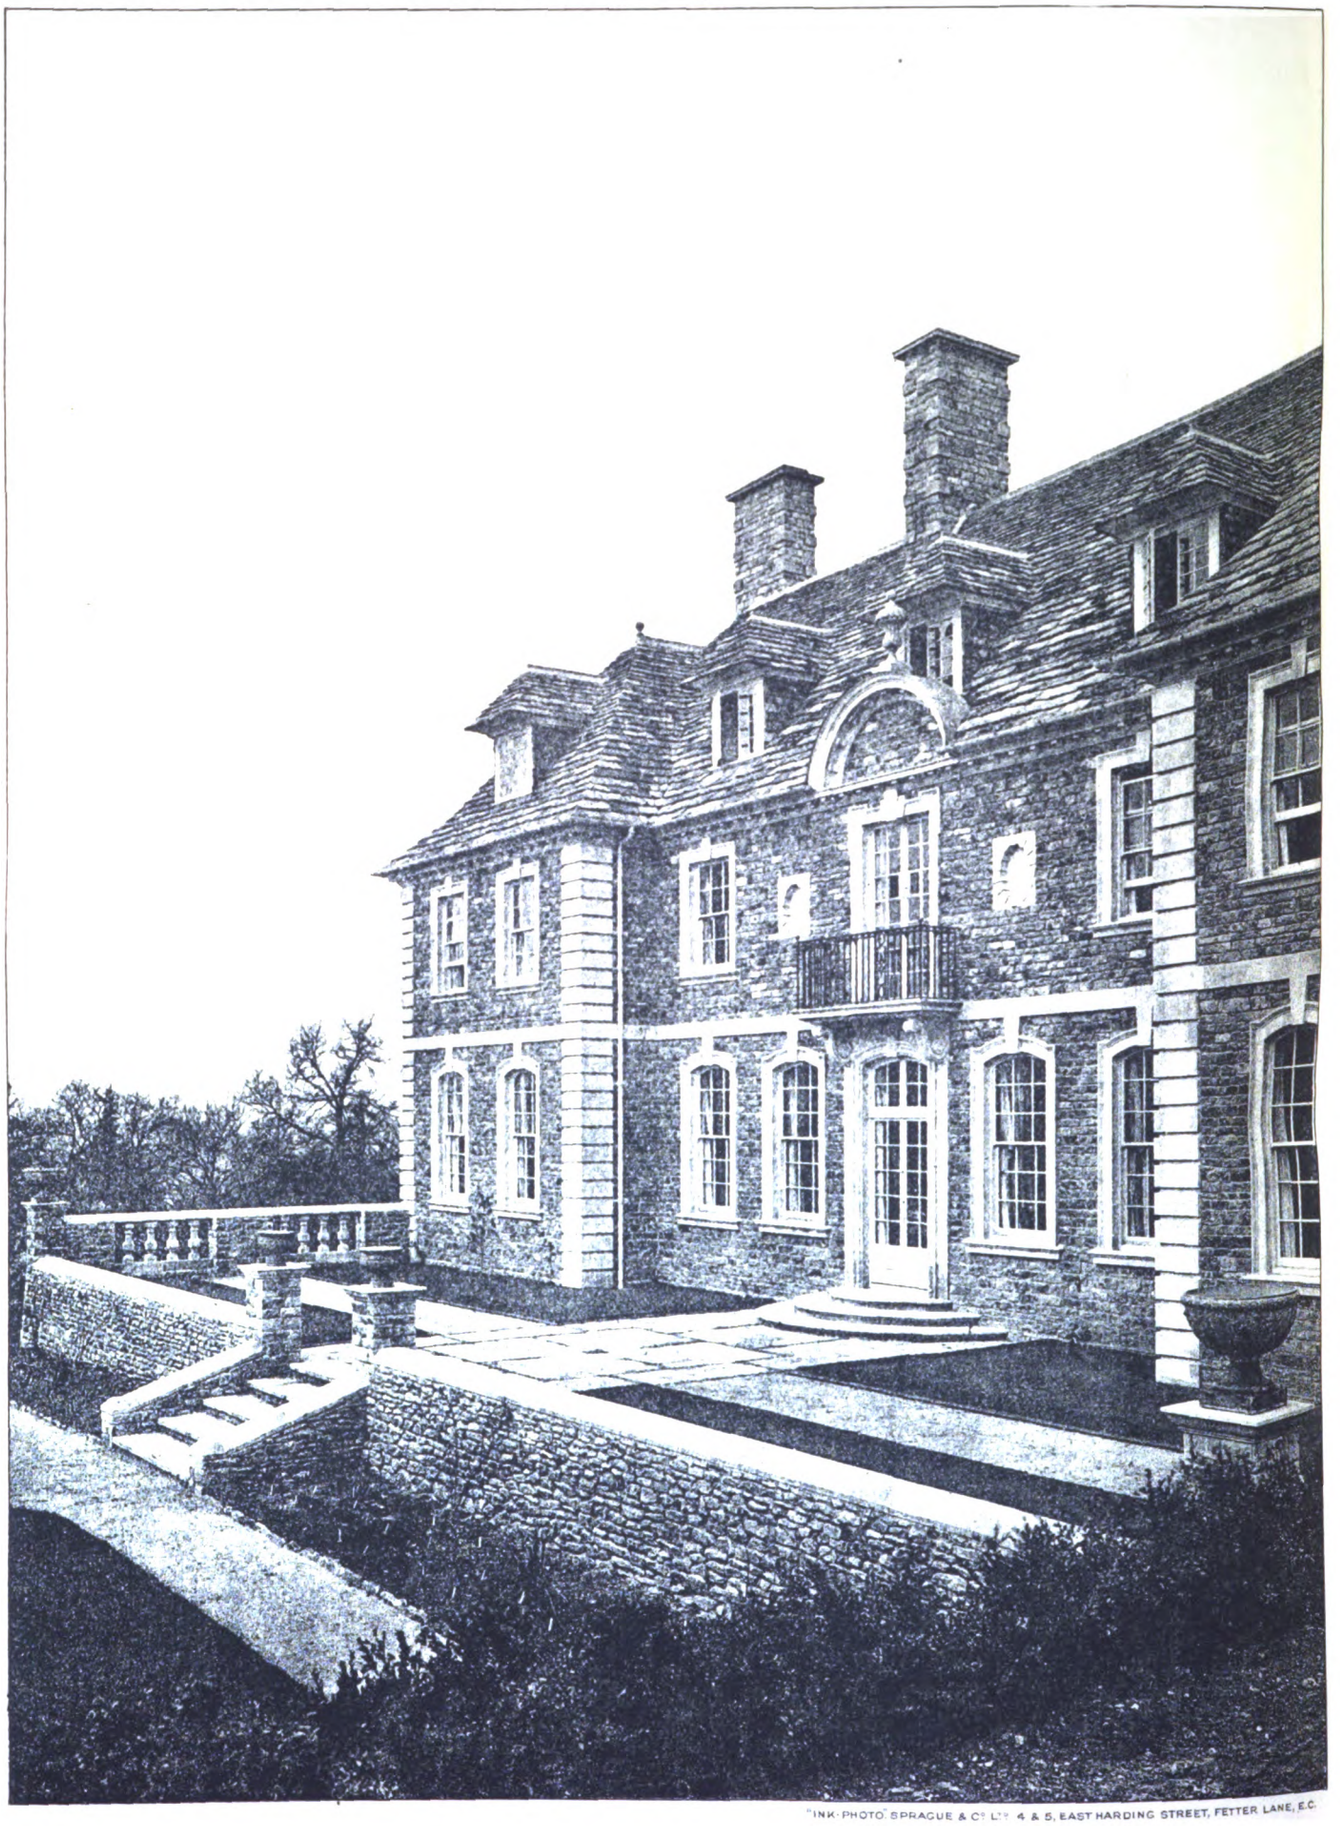
A little breeze seems to have been blowing amongst the municipal officials of Sheffield, a thing very likely to happen in the extension of municipal professionalism resulting from the assumption of universal municipal management or mismanagement of all our affairs. When one elected and unpaid body of citizens undertakes to regulate for their fellow citizens the supply of water, gas, milk, and everything else there must be a multiplication of officials whose spheres of influence sometimes overlap, and hence result friction, shelving of responsibility, assumption of dignity.

The advantages of mechanical filtration in lieu of the old sandbed system for dealing with the town supply of water has been recognised by the Edinburgh and District Water Trust, and that body is now constructing filtration works at Fairmilehead, and building a filter-house to contain twelve Bell's mechanical filters. Mechanical filtration has the advantages of quicker action, equal efficiency, lower initial cost, small expense in upkeep as compared with sand filtration. The disadvantage of these mechanical filters is the necessity for disposing of the dirt filtered out of the water. This is washed mechanically out of the filters, and has to be collected in settling tanks in order that it may be cleared away.

ILLUSTRATIONS.

CONKWELL GRANGE, WILTSHIRE.—FORECOURT AND MAIN ENTRANCE—KITCHEN COURTYARD AND SIDE ENTRANCE—THE GARDEN ENTRANCE TO SOUTH FRONT—ENTRANCE DOOR AND VESTIBULE, &c.—THE HALL—THE DINING-ROOM.

This charming house, of which Mr. E. Guy Dawber is the architect, is built in a wood on the slope of a hill some seven miles out of Bath. Much of the wood had to be cleared to form the gardens and terraces. The house commands beautiful views towards Savernake Forest. The kitchen gardens, stabling, lodges, &c., have all been arranged near by the house. The walls are built in coursed rubble of stone taken from old walls on the estate. All dressings and ashlar work are executed in Bath "Ridge" stone from the Corsham Quarry Co. The roof is covered with old stone slates procured in the neighbourhood. Mr. Francis Crarg, of Bath, executed the stone and wood carving. The general contractors were Mesrs. Walker & Slater of Derby. The following are among the sub-contractors:—Steelwork, Redpath, Brown & Co., London; casements and fittings, John Pye, of Moreton-in-Marsh; stoves and grates, Bratt, Colbran & Co., London; plumbing and sanitary fittings, Mellowes & Co., London; parquet floors, Bassant Bros., London; modelled plaster work, E. P. Bankart and George Cox; door furniture, Brawn & Co., Birmingham; railings, J. W. Singer & Sons, Ltd., Frome; heating apparatus, Wm. Gould, London.



Our illustrations of Queen's College, Oxford, will be continued next week.

HOUSE AT CHESHAM BOIS, BUCKS.

This house was designed and built for Mr. Monk, artist and etcher. The house overlooks Chesham Bois Common. The brickwork is five courses to the foot with old London tiles on the roof. Messrs. Henry Hope & Son supplied the steel casements and leaded lights. Mr. Monk had a very fine collection of old casement handles, and these were fitted to the new casements. The feature of the house is the studio, part of which is finished internally with Dutch bricks. The garden has been laid out in an unique manner, using London paving and Dutch clinkers for the paths, while the grey garden was designed and plants supplied by Miss Jekyll.

GREY AND WHITE MARBLE MANTLE, HOTEL DE LA CHANCELLERIE, YPRES.
From a Sketch by BANISTER FLETCHER.

STRESSES AND STRAINS IN GIRDER WORK.*

THE title of the paper I have the honour to read to you this evening was suggested to me by your energetic secretary, and I gladly accepted it in the belief that he was better acquainted with your requirements than I could be. It is interesting to note that from the time of the Britannia Tubular Bridge, 1845, when the theory of stresses first received general attention, to about the year 1880, it was customary to speak of the stresses in girder work as strains, so that Mr. F. Wentworth Shields's book on "Strains in Ironwork," and my own lectures to the Society of Engineers, with the same title, which dealt solely with stresses, did not at that time seem improperly named, as draughtsmen were in the habit of describing their preliminary work in designing a bridge as "taking out the strains," and as many of the leading "iron-men" in the various railway engineers' offices were old students of mine, I am afraid I must be held responsible for helping to keep up the misnomer. However, in my lectures just referred to I gave a full description of the true use of the terms, and I cannot do better than recapitulate that portion here. I said:—"By a load on any member of a structure is meant the aggregate of all the external forces acting upon it, including the weight of the member itself and of other parts supported by it; by a strain is meant the change of form produced in a piece by the action of a load; and by a stress is meant the resistance set up in the material by its molecular forces opposing the action of a load in producing a strain. Thus the strength of a piece in a given position may be such that a load of so many pounds produces a stress of so many pounds per square inch, the result being a strain, or change of form of a certain amount, whether temporary or permanent, and, when large enough, appearing as stretching, shortening, bending, crumpling or twisting. The term strain is commonly used instead of stress, and is usually meant as such when we speak of the calculation of strains; so that although we may use this term as an ordinary office phrase, we must bear in mind the distinction when we make a systematic study of the subject."

The various kinds of strain that may come upon a structure are:—

1. Tension: stretching, pulling, tearing.
2. Compression: crushing, pushing, squeezing.
3. Shearing: cutting, nipping, or when acting along the grain of wood it is called detrusion.
4. Transverse strain: cross strain, bending, deflection. This strain may be resolved into tension, compression and shearing, as we shall see later on.
5. Torsion: twisting, wrenching. This strain is a form of shear which belongs almost exclusively to machinery.
6. Buckling or crumpling, which is a compound strain made up of crushing and bending.

At the present day it would, of course, be taken as a sign of ignorance if we spoke of strains when we meant stresses, as the whole subject is now fairly well understood by the ordinary draughtsman.

I have here a model beam in indiarubber which will help us to understand a good deal about stress and strain. One side is plain, the next is divided throughout the length by parallel lines ¼ inch apart across the beam; the next side has squares of ⅜ inch all over it; and the fourth side is covered with circles ½ inch diameter. When I bend the beam double and turn it sideways you will see that the outside of curve is hollow and the sides bulge considerably on the inside of the curve, due to the effects of tension and compression respectively. A bar of iron of the same size bulges in just the same way when bent double. Now turning the parallel lines towards you and bending the beam, you will see that the lines come closer together towards the concave edge and go further apart towards the convex edge, while in the centre of the depth the spacing remains unaltered. This shows you that when a beam is supported at the ends and loaded on the top the upper part is greatly compressed; this compression, which is a measure of the compressive stress induced in the beam, gets less and less towards the middle of the depth, where it disappears, and below that the action is reversed, so that the material is stretched more and more until the bottom is reached, where the tension becomes a maximum. The middle of the depth where the strain disappears is called the neutral layer, and the line this would present in a cross section is called the neutral axis. So far we have only seen the effect of the longitudinal stresses, but turning the side with the squares towards you and bending the beam the squares will be found to become lozenge-shaped in opposite directions on each side of a vertical centre line. This shows the diagonal effect of the real stress, which takes shear into account as well as tension and compression. The side with the circles upon it shows this also, but perhaps in a more interesting manner, as the circles become ellipses with the long axis in the direction of the greatest stress. This model may also be used to show the compression which a column undergoes from an axial load, and the compression and tension from a non-axial or eccentric load. It will also show the effect of torsion, the relative movement of the particles being indicated by the change of shape of the squares and circles.

Now I am afraid we must come to a part of the subject not quite so interesting, but the apology must be that it is essential. I refer to the subject of bending moments. A bending moment is the effect of a load or its reaction at the supports, multiplied by the leverage with which it acts; in other words, it is the active part of the calculations, or the effort, as distinguished from the resistance due to the nature of the material and the disposition of its parts. The bending moments, however, do not tell us all the action that is taking place; we have also to take account of shear, and this is a matter which does not always receive due consideration. Many of the failures in early ferro-concrete work were due to the neglect of shear, and only recently the question of shear in masonry dams has been subject to investigation by many distinguished men.

I have now some lantern slides to illustrate the subject. The first figure shows a beam supported at the ends and loaded in the centre (diagram 1). The next shows the beam with lines on the side, originally parallel, but now closer together at the top and further apart at the bottom on account of the bending, indicating the longitudinal stresses of tension and compression. The next figure is an attempt to indicate the nature of vertical shear in a beam under the action of a load. It does not really divide up into blocks, as shown, as the effect is continuous throughout the beam, any series of particles in a vertical section tending to separate by

* A paper read before the Association of Engineers-in-Charge on April 14, by Henry Adams, M.Inst.C.E., M.I.Mech.E., Vice-President.

Digitized by Google

sliding from the adjacent particles. Horizontal shear is shown in the next figure, and this can be illustrated more naturally, because if we put half a dozen boards together to carry a load they will visibly slide on each other as shown. The corner figure shows by a series of curves what is approximately the true distribution of stress throughout a solid beam carrying a load. On the right-hand side we have a diagrammatic view of a girder under a concentrated central load and an equal uniformly distributed load. The girder is shown by a thick line only, as what we are now considering does not take account of the material construction; it may be a solid beam or a flanged girder, but it makes no difference at present.

The bending-moment diagram for the central load is a simple triangle whose depth is $= \frac{Wl}{4}$.

Where W = total load in tons.
l = span in inches.

Vertical ordinates or depths at any part of the triangle indicate the amount of bending moment at the corresponding part of the beam. When the same load is equally distributed along the beam the bending-moment diagram becomes a parabola, as shown, the depth in the centre being $\frac{Wl}{8}$, or exactly half that due to the same load concentrated in the centre. Ordinates within the parabola at any point give the bending moments at corresponding points of the beam as

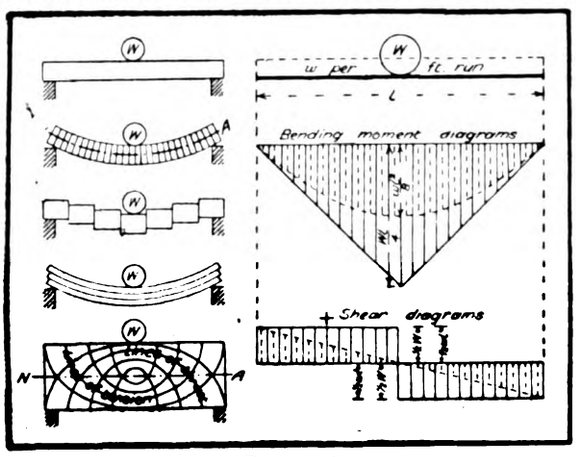

DIAGRAM 1.

before. The lower figure shows the shear diagrams for the same loads. That from the concentrated load is uniform throughout, the depth being equal to the reaction at either support, or $\frac{W}{2}$. The construction of a shear diagram for any load is very simple. If a start be made at the left-hand support with a shear stress equal to the reaction at that support, and the same length or ordinate is maintained until a load is reached, and then the ordinates are reduced by the amount of the load, and so on until the other support is reached, then the whole diagram will be formed. In the case of a concentrated central load, the ordinate will change from a plus value above the line to an equal minus value below the line. The terms plus and minus merely signify the position of the ordinates with regard to the line of origin, and do not indicate any difference in the nature of the shear. The question is frequently asked, "What is the shear exactly under the load?" The answer is that on the centre line of the load the shear changes from plus to minus, so that the centre line being taken as a geometrical one "having length without breadth," the change is immediate, and there is no point where both can be measured at the same time.

Following this method for a uniformly distributed load the ordinates begin to change directly the support is left, so that the complete outline forms two triangles, indicating that the shear stress is equal to $\frac{W}{2}$ at each support, the same as with a concentrated load, while it gradually diminishes to zero at the centre. To facilitate the work in the case of irregular structures, it may be useful to note that the bending moment at any section of a beam is equal to the area of the shear diagram up to that point measured on the length-load scale adopted, due attention being given to the plus and minus values of the shear diagram.

With this explanation you will be able to follow readily the bending moment and shear diagrams for all the regular conditions of loading and supporting, and these will be thrown upon the screen, so that any further points of interest may be described.

Fig. 1 (diagram 2) shows a cantilever loaded at the end, with the bending moment and shear diagrams. The maximum bending moment is $= Wl$, and the shear $= W$, uniform throughout.

Fig. 2 shows a cantilever with three concentrated loads, W, W_1 and W_2, at different points. The principle of constructing the bending moment and shear diagrams will be easily followed from the previous description.

Fig. 3 shows a cantilever under a uniformly distributed load. The maximum bending moment is only half that due to the same load concentrated at the end, and the shear stress being reduced from the support outwards in proportion as the load is passed becomes zero at the end.

Fig. 4 shows a cantilever carrying a concentrated load at the extremity and also a distributed load. The diagrams will be seen to be made up of figs. 1 and 2, where similar loads were taken by themselves.

Fig. 5 shows a cantilever with a partially distributed load. The construction of the bending-moment diagram is rather interesting. First the parabola is drawn for the load as if the cantilever extended out for the length z; then the outline is continued by drawing the triangle of ordinates as if the load were concentrated at its centre of gravity.

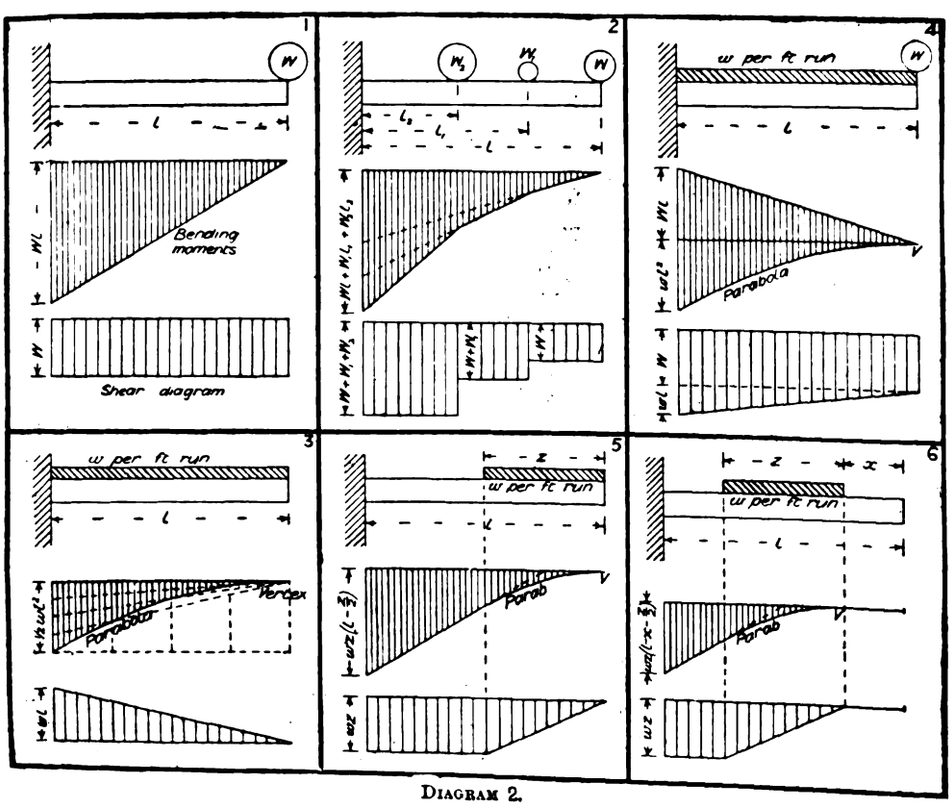

DIAGRAM 2.

Fig. 6 shows a cantilever with a partially distributed load not reacting to the outer end, and the diagrams are similar to the last, supposing the cantilever to terminate at the outer end of the load.

Fig 7 (diagram 3) shows a beam supported at the ends and carrying a concentrated load in the centre.

Fig. 8 shows a similar beam with the load shifted out of the centre.

Fig. 9 shows how two concentrated loads on a beam are dealt with. In the alternative bending moment diagram the overlapping of the dotted independent diagrams for each load being allowed for gives the same lengths of ordinates as the upper diagrams, although its shape is somewhat different.

Fig. 10 shows a beam supported at the ends and carrying a uniformly distributed load.

Fig. 11 shows a beam carrying a partially distributed load with rather a neat form of construction

Digitized by Google

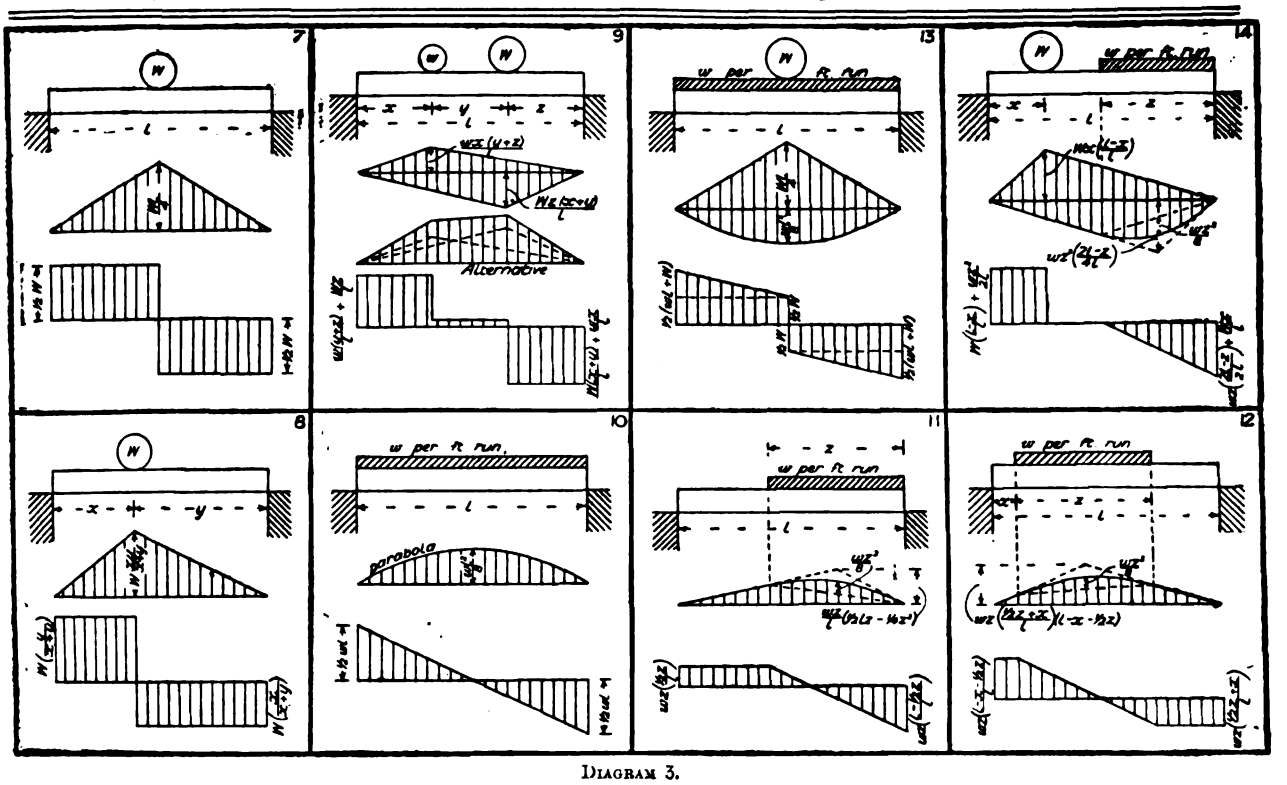

DIAGRAM 3.

for the bending-moment diagram. The load is first assumed to be concentrated at its centre of gravity and the main triangle drawn; then the apex is cut off by a chord line extending to each extremity of the load, and a parabola due to the distributed load drawn upon it.

Fig. 12 shows a beam with a partially distributed load not reaching either end.

compression stress in lower. The nature of the longitudinal stress is also shown in the elevation by the thick lines for compression and thin for tension, the terminations marking the points of contrary flexure where the bending moment is zero.

Fig. 16 shows a similar fixed beam with a uniformly distributed load. The bending-moment diagram depends to

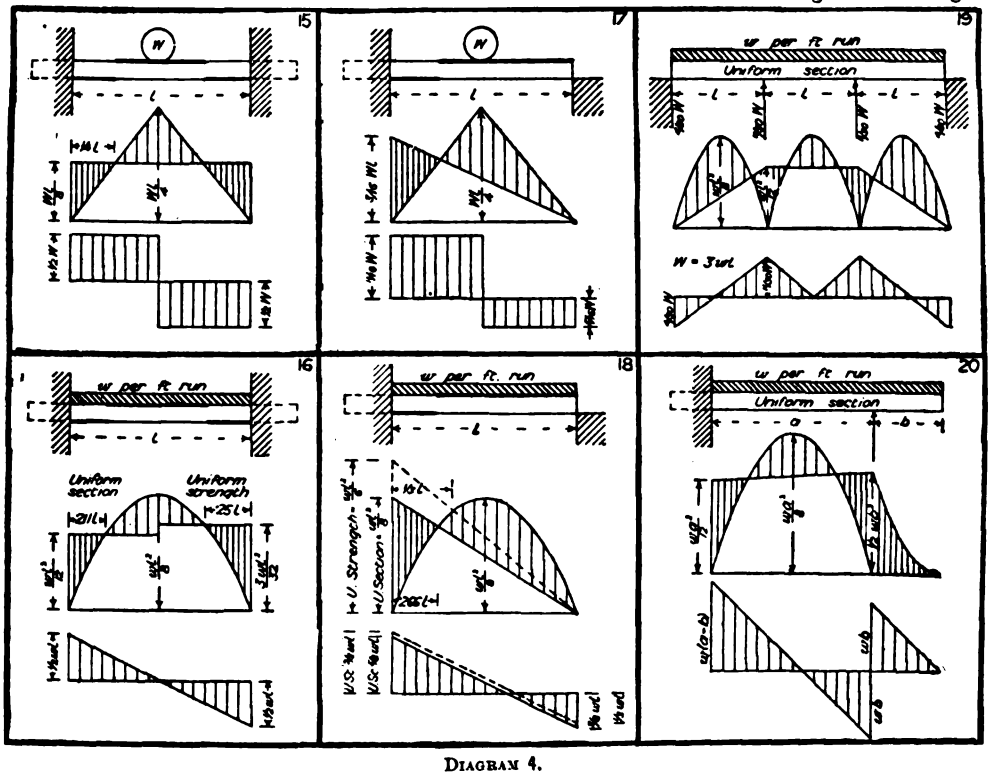

DIAGRAM 4.

Fig. 13 shows a beam carrying a concentrated load in the centre and also a uniformly distributed load.

Fig. 14 shows a beam carrying a distributed load over one half and a concentrated load on the other half. It will be seen that the portion of the girder between the two loads has no shear, according to the rules laid down. This happens because the two loads are assumed to be equal and their centres of gravity equidistant from the supports.

Fig. 15 (diagram 4) shows a beam with the ends sufficiently built in the walls, or carried continuously over supports, or otherwise secured, so that they are in the technical condition known as "fixed." The narrow spaced ordinates in the bending-moment diagrams show tension in upper side and some extent upon the construction of the girder in this case, as to whether it is of uniform section or uniform strength.

Fig. 17 shows a beam fixed one end and merely supported at the other end, with a concentrated load in the centre.

Fig. 18 shows a similarly fixed and supported beam, but carrying a distributed load.

Fig. 19 shows a "continuous beam" or girder with more than two supports.

Fig. 20 shows a beam in the condition of a gallery cantilever, one end fixed and the other projecting over a column or other support. The lettering in every case shows how the diagrams may be calculated and set off to scale.

TESTS ON BRICK AND TERRA-COTTA COLUMNS.

PROFESSOR ARTHUR N. TALBOT, of the University of Illinois, assisted by Mr. Duff A. Abrams, Associate in theoretical and applied mechanics, has published a report on a series of tests carried out at the Engineering Experiment Station of the University. The experiments were conducted on sixteen short columns or piers of brick and sixteen columns built of hollow terra-cotta blocks not filled with concrete. The length of the columns varied from 10 feet to 12½ feet. In lateral dimensions the brick columns were 12½ by 12½ inches, and in the terra-cotta block columns the range was from 8½ by 8½ inches to 17½ by 17½ inches. The bricks used in the construction of the columns were of two grades—an excellent class of building brick and a soft grade selected as representative of inferior brick. The average compressive strength of the former bricks was in pounds per square inch 10,690, and the modulus of rupture under transverse stress was 1,670 lb. per square inch, whilst the inferior bricks had an average compressive strength of 3,920 lb. and a modulus of rupture of 481 lb. The terra-cotta blocks were of good quality. Different qualities of mortar and different grades of workmanship were used. The loads were applied continuously to failure in most cases, but tests were also made with repeated applications of the same load. Central loading of the columns was used in most cases, but in some tests the load was applied eccentrically. The following is the summary of the results as given in the report:—.

"Both brick columns and terra-cotta block columns gave high strengths in all cases where strong mortar and care in building were used. For central loading the strength of the brick columns ranged from 3,220 to 4,110 lb. per square inch, and the strength of the terra-cotta block columns from 2,700 to 3,790 lb. per square inch, the columns having the highest resistance not failing at the full capacity of the machine. The effect of the strength of the mortar is apparent in the carrying capacity developed in the columns; lower loads were found in columns built with 1-5 Portland cement mortar than in those with 1-3 Portland cement mortar, still lower loads in those with 1-3 natural cement mortar, and still lower loads in those having 1-2 lime mortar. The effect of the quality of the brick is shown in the columns made with inferior brick, which carried only 31 per cent. as much as columns built with the better grade of brick. In the case of the terra-cotta columns, the blocks which were culled out as somewhat inferior gave a column strength perhaps 30 per cent. less than the columns built with superior blocks. The effect of the attempt to represent hurried or careless workmanship in two brick columns and in three terra-cotta block columns was a loss in strength of about 15 per cent. and 25 per cent. respectively.

"The ratio of the strength of the columns to the compressive strength of the individual brick and block is of interest. In the well-built brick columns loaded centrally the ratio of strength of column to compressive strength of individual brick ranged from 0.31 to 0.37, and in the underburned clay-brick column the ratio was 0.27. In the terra-cotta block columns with central loading the ratio of strength of column to that of individual block was 0.74 for the incompleted test and 0.83, 0.85 and 0.89 for the others. If, as seems to be the case, the strength of the brick or block to resist cross-breaking is an element in determining the strength of the built-up column, a deeper or thicker brick would give higher column strength. It is possible that this partially accounts for the fact that the ratio is found to be higher for terra-cotta block columns than for brick columns. The tests suggest that the ability of individual pieces to resist transverse strength is an important element in the strength of the completed column. This suggestion may have an important bearing on the advantageous size of the component blocks which may be used in a compression piece where high strength is desired.

"The strength of the column is greater than the strength of the mortar cubes in both brick and terra-cotta block columns, excepting only the soft brick columns which had brick of low compressive strength. It is evident that the strength of individual brick or blocks and the strength of the mortar both enter into the resistance of the column. The relative effect of the two depends upon the character of the material. It is evident, however, that the better the individual piece the more important it is to have the mortar of high resisting strength.

"The results obtained in applying the load eccentrically were found to agree very well with those obtained from ordinary analysis. When the amount of eccentricity in the application of the load is known or may be estimated closely, the ability of the column to resist this action may be calculated quite closely. It is apparent from the results that the calculated resisting stress in the column on the side of maximum compression is higher than that which causes failure in centrally loaded columns. The higher stress developed with eccentric loading is probably due to the influence of the restraint of the less stressed interior portion. The tests made by applying and releasing a single load a number of times gave failures at loads below those which produced failure in similar columns at a single application of the load. The phenomenon is common in materials of the nature of brick and terra-cotta.

"It is apparent that the quality of workmanship in laying up such columns has an important bearing upon the resisting strength. The work of building columns, however, is not difficult and requires only ordinary care. Full joints and an even bearing are important, and the ordinary workman ought to be able to construct columns of high strength. In the tests made on columns intended to represent poor or careless workmanship the decrease in strength was not as much as anticipated. However, it must be understood that careful and trustworthy work is essential and that a few poor joints will materially reduce the strength of the structure. Wherever good material and good workmanship are insured the strength of masonry of this kind may be utilised with advantage."

TEST OF THREE LARGE REINFORCED CONCRETE BEAMS.

AT the Engineering Experiment Station of the University of Illinois, Mr. Arthur N. Talbot, Professor of Municipal and Sanitary Engineering, and in charge of theoretical and applied mechanics, has carried out some highly interesting experiments on perhaps the largest reinforced concrete beams yet tested, chosen almost at random from a large number of beams made up for use in a railroad structure, which may thus be considered to be representative of actual conditions of construction. The slabs were supported on balks of timber and were tested in pairs, being kept 12 inches apart by oak beams. Pressure was applied by means of hydraulic jacks. From the Professor's report we give the following extracts:—

1. *Materials.*

The information and data on the materials used and the methods of fabrication were furnished by Mr. Gaut of the Illinois Central Railroad, and as there was no thought of needing results for test discussion, no special measurements or analyses were made, only the attention usual in well-made construction work being given. The sand was torpedo sand of good quality from Merom, Indiana. The stone was unscreened crushed limestone from Chicago, the largest size being two inches. The cement was Owl Portland cement manufactured by the German-American Portland Cement Company. Tests of the cement gave a tensile strength of 822 lb. per square inch for the seven-day neat test; 95.2 per cent. passed the No. 100 sieve.

The main longitudinal reinforcing bars were 1 inch square corrugated bars, new style. Tests made by Robert W. Hunt & Co. of the bars used in this work show an elastic limit varying between 51,260 and 52,770 lb. per square inch. The ½-inch bars used in the top longitudinal reinforcement were cup bars. Tests showed these to have an elastic limit ranging from 45,800 to 51,100 lb. per square inch. The stirrups were ½-inch cup bars.

2. *The Slab and its Reinforcement.*

The general size of the slab was 6 feet 3 inches breadth by 25 feet length. One-half of the length had a general thickness of 34 inches, and the other one-half sloped from the middle to a thickness of 31 inches at the end. This difference in thickness was for the purpose of facilitating drainage. In addition to the thickness just mentioned there was an additional inch at the bottom at either end for a distance of 18 inches, the width of the bearing area. This arrangement permits a better appearing joint at the supports. The estimated weight of one of the slabs is 33 tons.

The longitudinal reinforcement was placed with the lower face of the bar 3 inches from the bottom surface of the slab. This makes the distance from the centre of the reinforcing bars to the top of the slab at the middle 30½ inches. Although the depth to steel is less than this for one half of the beam, the maximum bending moment is at the middle, and 30½ inches will be used in the calculations, both in calculating the resisting moment and in calculating the shearing stresses. This is admissible in the

Digitized by Google

latter case because of the slope of the upper surface. Twenty-nine 1-inch bars were used in each slab, the spacing being 2½-inch centres and 2½ inches from the lateral faces. Counting the depth to the centre of the steel as 30½ inches, the reinforcement amounts to 1.27 per cent.

Two methods of placing the reinforcement and providing against diagonal tension were used. In No. 70 no stirrups were used and the bars were bent up at an angle of about 45 degrees rather close to the end. The bend for one-fourth of them started at about 2 feet from the end, for another one-fourth at 3 feet, for another one-fourth at 4 feet, while the remaining bars were straight throughout the length of the slab. No. 70 was the last slab made in this way. In the slabs made after No. 70 (including No. 71 and No. 72) stirrups were used and the bars were bent up farther back from the end and less abruptly, giving a better distribution of the reinforcement. In one-fourth of the bars the inclination started at a point 6 feet from the end, in one-fourth at 4 feet from the end, and in one-fourth at 2 feet from the end, while as before the remainder of the bars were horizontal. In these slabs U-shaped stirrups, made of ½-inch cup bars, were placed vertically at distances of 2½ feet, 4 feet, 5½ feet and 7 feet from the ends of the slabs. Each stirrup passed under and included five reinforcing bars and reached nearly to the top of the slab. In addition to the main reinforcing bars, four ½-inch cup bars were placed longitudinally 3 inches from the top of the slab, and transversely across the slab just above these were twelve ½-inch and six 1-inch bars, while transversely across the bottom face just above the longitudinal reinforcement were twenty-one ½-inch bars. As the top reinforcement is only one twenty-fifth of one per cent. it is not considered in the calculations of neutral axis position or of compressive stress in the concrete.

At the middle of the width of the slab and 2 feet 6 inches from either end, heavy steel stirrups were anchored in the concrete. These were designed to receive the device by which the slabs were lifted and placed.

3. *Composition and Fabrication.*

The proportions of the concrete were one cement, two sand and five broken stone. The concrete was mixed in a No. 2 Smith machine mixer. There was no measurement of the amount of water used, but the concrete was mixed so wet that little or no tamping was required, or even feasible. The forms were strong and substantial and were well braced. The main longitudinal reinforcement was carefully placed and held by wires and blocks until the concrete was in place. The stirrups were held likewise. It is probable that more mortar was used in space below the bars on account of the difficulty in working around the bars, but there was no attempt made to vary the mixture in the slabs. The concrete was well spaded and stirred, especially around the reinforcing bars.

4. *Storage and Age.*

The slabs were left where made, exposed to the weather, from the time of fabrication until tested. The sides of the forms were removed after forty-eight hours. No. 70 was made October 7, and No. 71 and No. 72 October 8, 1907. The test of No. 70 was made April 15, and of No. 72 April 28, 1908. No. 71 was used in both tests. The slabs were therefore more than six months old. On account of the temperatures prevailing during the winter, the setting of the concrete during much of the time must have been slow, and the conditions were probably less favourable for hardening than is the case in ordinary ninety-day laboratory tests.

5. *Manner of Failure.*

The manner of failure was quite different in the two beams, No. 70 and No. 72. In the case of No. 70, although it is evident from calculations that the steel of the reinforcing bars had nearly reached the yield point, there was no evidence of this in the appearance and action of the beam at the time of failure. At a load of 593,000 lb. the main diagonal crack outside of one load point was seen to be extending rapidly, and at 734,000 lb. it was opening wide. It was evident for some time that the beam was on the verge of total failure. Finally it failed suddenly by diagonal tension, so called shear failure, at an applied load of 801,000 lb., the diagonal crack having suddenly extended to the top of the slab and opened wide. At the same time the horizontal crack which had formed along the reinforcing bar (by the action of vertical tension) lengthened and the bar pulled away from the concrete above. The characteristics of this test were the formation of main diagonal cracks at either end and the final sudden failure of the beam by diagonal tension.

In No. 72 the presence of the stirrups and the changed position of the reinforcing bars at the ends were sufficient to resist the diagonal tension developed. Although the diagonal cracks were numerous and although some of them finally extended to within 12 inches of the top face of the slab they remained small and fine and were well distributed. They lacked the growth and concentration which are apparent in failures by diagonal tension. The tension cracks in the middle third of the beam extended upward as the load was increased and at 811,000 lb. nine of these were visible to within 12 inches of the top of the slab. At this load the tension cracks were opening wide, indicating that the yield point of the reinforcing steel had been passed. Above 800,000 lb. the deflection increased rapidly. The maximum load applied was 840,000 lb., the indicated load then falling off when the deflection was increased. It seems evident that a load of 811,000 lb. would not have held long, and the maximum load applied held but momentarily. The characteristic of the test of No. 72 was slow failure by tension of the steel, without sign of compression failure and without sign of impending failure by diagonal tension. The effectiveness of the stirrups and the bending of the bars at ends are evident in this test. This is the more important as the diagonal tension failure may give little warning and may develop with repetitions at lower loads. It may be noted that on the next day the test was continued until there was a deflection in No. 72 of 3½ inches, the load applied ranging somewhat under 800,000 lb. Upon release of load there was a recovery of 1 inch in the deflection. At this time the stretch of the steel and the consequent concentration of the compressive stress were so much that there was considerable crushing of the concrete. Slab No. 71, which was used as the lower beam in both tests, seems not to have suffered from the first test, the cracks closing up upon release of load. In the second test the tension cracks opened up at the maximum load and there was evidence of the steel being stretched beyond the yield point. It should be noted that on account of its inverted position and the location of the supports the bending moment developed in the lower beam was somewhat smaller than that in the upper beam. There was no sign of impending failure by diagonal tension.

6. *Compressive Stress in the Concrete.*

The compression in the upper fibre, calculated by the ordinary methods, runs up to a high figure, as is usual in tests of beams having a considerable amount of reinforcement and adequate provision for web stresses. Assuming the neutral axis to be 0.43 of the depth to the reinforcing bars and using the ordinary straight-line formula, the compressive stress in No. 72 at the maximum load was 3,190 lb. per square inch. Using the parabolic formula and considering that the compressive deformation is one-half of the ultimate compressive deformation of the concrete, the calculated stress is 2,870 lb. per square inch. Even at this high calculated stress there was no sign of compression failure and none was apparent until after the steel had stretched beyond its yield point. Comparing the deformation developed with that of other tests it seems probable that the beam would have taken at least one-third more compressive stress before failure in compression at first load would have resulted. Of course, repeated applications of any such high load might soon have injured the beam. A further evidence of the strength of the concrete is seen in the later test referred to, where after the maximum load had been reached and the steel was stretched well beyond its yield point the beam held a load of nearly 800,000 lb. until the deflection reached 3½ inches before any considerable amount of crushing of the concrete took place.

7. *Remarks.*

The tests showed that the concrete was of excellent quality and that the slabs acted similarly to high-grade test beams made and tested in laboratories. The uniformity and regularity of these large beams were shown in various ways in the tests. As these particular slabs may be presumed to be fairly representative of the slabs fabricated for the work, the tests ought to add confidence in the quality and soundness of the reinforced concrete used in this work, and in other work of large magnitude made under as careful conditions. The action of the concrete in compression under the high stresses developed was quite satisfactory. The tests show the effectiveness of stirrups and of the methods used in bending up bars at the ends in resisting diagonal tension. Diagonal tension weakness is particularly undesirable because of the possibility of sudden failure and of injury after repeated applications of the load and because of the difficulty of detecting incipient failure when the sides of the beam are

Digitized by Google

not available for inspection. Ample safety against these conditions is important and means should be provided to resist the diagonal tension. Failures by tension of the steel and by compression of the concrete give warning through abnormal deflections and in other ways and are less likely to lead to serious results. Also, it seems evident from these tests that the action and properties of reinforced concrete beams made under efficient supervision do not differ much from those of laboratory test beams.

The following tables summarise the information obtained from the experiments:—

The calculated stress in steel and the calculated vertical shearing stress include the stress due to weight of slab.

ART EXHIBITIONS.

VISITORS to the New Gallery are intended to commence with the paintings in the South Room, then to turn to the West Room, and lastly to make the tour of the North Room. The hanging committee seem to have put their most attractive wares in the first gallery, and to have considered the two later galleries of secondary importance. By this we do not mean that these are treated like a lumber-room, for the standard is too high; but the first gallery contains a larger proportion of noteworthy pictures than either of the other two. Even there that proportion is not a very great one, for though the twenty-second Summer Exhibition contains much that is excellent, it is rather lacking in works of striking force. One reason for this is that this year a change has been inaugurated in the usual arrangement. The Summer Exhibition is to be divided into two sections—the first, from April 17 to June 12, consists of new works, not previously exhibited in London, while the second, from June 21 to August 14, may be to some extent retrospective.

Individualism is shown in many of the pictures in the South Gallery, and with greatly varying results. One of the first to arrest attention is *The Farewell*, by Mr. F. Cayley Robinson, which is unlike anything else shown. There is such unmistakable ability that the spectator is in doubt whether to ascribe the treatment to affectation or to genuine impulse; in either case it has the power to charm

Digitized by Google

though of a kind that if repeated often would sooner or later prove wearisome. The subject is but indifferently explained by the title; possibly the artist calculated on a certain amount of artificial interest being aroused by that uncertainty. Mr. G. Spencer Watson has sent three contributions, each pleasant to see. *Cupid and Psyche* is in its way as spontaneous as No. 49, *A Study*. The latter picture suggests that Mr. Watson set out to paint a conventional portrait, but was tempted from orthodoxy by his sitter coming under the sway of some strong emotion. Mr. R. Anning Bell is most restful in the subject and treatment of No. 16, which illustrates certain lines in a "Midsummer Night's Dream." *Vittoria Accoramboni, the White Devil*, is a bold work by the Hon. John Collier, which shows a handsome bejewelled woman three-quarter length, magnificently robed, and resting on a marble seat. Mr. E. Reginald Frampton suggests in his *L'Enfant Jeanne d'Arc*, that the romantic temperament of the Maid of Orleans could scarcely have escaped influence from the romantic environment of her childhood, and that the landscape at her feet might have been as influential as any heavenly voices.

The West Room has three portrait subjects of note, viz. *A Study*, by Mr. Watson (already alluded to); *In the Dunes*, by J. J. Shannon, A.R.A., and *The Motor Bonnet*, by John Lavery, R.S.A.; and we are tempted to include No. 61, by Mr. H. de T. Glazebrook. Both Mr. Lavery and Mr. Shannon have taken a welcome liberty with their subjects and departed from rigid portraiture. Mr. J. J. Shannon is more conventional, though scarcely less successful, in his presentment of *Mrs. Douglas Vickers*, in the North Room. This latter room has many interesting, though few important pictures. An exception is Mr. E. A. Hornel's *The Blackbird's Song*, which presents his curious treatment at its best. *The White Mill*, by Mr. E. A. Walton, should be a constant invigorator to its fortunate owner. Nearly all the familiar contributors to the New Gallery are represented, and constant visitors will have little ground for dissatisfaction.

The Central Hall is, as usual, devoted to sculpture and handicrafts. In the balcony are drawings, etchings, and handicrafts. The etchings of Mr. Theodore Roussel are particularly deserving of attention.

A singularly happy spring exhibition is to be seen at the Leicester Galleries, Leicester Square, W., where a room is given up to some fifty pictures by Arnesby Brown, A.R.A., and fancifully entitled "The Changing Hours." It might be called without disrespect eminently "seasonable," for the pictures carry the spectator to the open pastoral country at a time of year when his mind is probably more affected by Nature than at any other. It may be truly said that they are full of atmosphere, for they concentrate and embody all the vague emotions that spring up on the contemplation of a flat and peaceful landscape bathed in sunlight or toned down by the subtle approach of dusk and sunset. But the present small exhibition shows Mr. Brown as something more than a painter of pastorals, for his subjects are reminiscent of other months than July and of other places than level fields. Each and everyone is full of the fascination of the country, and they make the room an oasis in London. The catalogue has an introductory "Conversational Note" by Mr. C. Lewis Hind. We fail to see the necessity or advantage of this dialogue form, and we think it would have been better treated as ordinary essay.

Mr. Frank O. Salisbury has attracted considerable attention by his works. What we take to be his first one-man show is being held at the Doré Galleries. The effect on entering the principal room is rather overwhelming, for none of the pictures are sparing in colour; and while among the works at the Royal Academy they might be an admirable contrast to their less daring neighbours, they seem to form a somewhat exuberant whole. Mr. Salisbury can paint portraits successfully, but, unlike many of his fellow-artists, he does not devote himself to that lucrative side of his art. His talents find a wider play in such works as the large "Passing of Queen Eleanor," which reveals a temperament that is not daunted by petty thoughts of size and acceptance. The subject-pictures are all decorative, and the same feeling enters into the portraits. The artist will no doubt build up a popular reputation.

A New Scientific Society, with the title of the Institution of Colliery and Mining Electrical Engineers, is to be formed The object of the new institution is to secure greater opportunities for discussing matters of importance to electrical engineers in charge of colliery installations. The opening meeting in Manchester will be held on Saturday next.

NOTES ON BOOKS.

"Galicia, the Switzerland of Spain." By Annette M. B. Meakin. (London: Methuen & Co. 12*s*. 6*d*. net.)

GALICIA is perhaps, to Englishmen of the present day, the least known of all the provinces of Spain, and yet it is very easily reached by the Royal Mail Steam Packet Co.'s excellent boats from Southampton to Vigo. The Bay of Biscay is not always rough; indeed, though we have crossed it several times, we have never seen it so. In mediæval times, when Compostella was the bourne of crowds of pilgrims, it was so much frequented by English travellers that a guide book was published in the fourteenth century entitled "The Way from the Lond of Engelond unto Sent Jamez in Galiz."

Not only is Galicia full of beautiful scenery, but, what more immediately concerns us, it contains a wealth of interesting architecture, as may be gathered from the numerous photographs in the book before us. Although these are small and apparently very largely the products of a hand camera, they tell the reader, and especially the architectural reader, enough to make him realise that the architecture of Galicia is well worth study.

The great architectural masterpiece of Galicia is, of course, the famous cathedral of Santiago de Compostella, and this our authoress describes and illustrates very fully, *inter alia* demolishing the theory that it was copied from S. Sernin at Toulouse, and suggesting, what seems to us probably correct, that both S. Sernin and Santiago were influenced by Cluny, which we know to have been the great architectural university of Western Europe at the time these churches were built. French influence was undoubtedly strong in the early mediæval period in this part of the peninsula, not only in Galicia, but in the north of Portugal, which anciently belonged to the kingdom of Galicia. Braga, for example, and still more Alcobaça, show distinct French feeling. We should not, however, on this account, assume that all the architects of Galicia were Frenchmen, and may admit that Maestro Mateo, the architect of the Portico de Gloria of Santiago, was a Gallegan.

The cathedral of Santiago is not the only excellent piece of architecture in the city; this also contains the palace of Gelmirez and the charming Plateresco work of the Royal Hospital, where also we find examples of that latest phase of Gothic work of which Spain and Portugal have the monopoly. The Colegiata de Sar must not be taken by Mr. Goodyear as supporting his theory of refinements, for there is little doubt in this case that the obliquity is the result of the water beneath the foundations.

The architect visiting Galicia should not give all his time to Santiago. Noya, Pontevedra, Orense, Celanova, are all well worthy of a visit. Many phases of ancient work, from prehistoric cup-writing to the extravagances of Churrigueresco, can be studied in Galicia, and the pleasures of anticipation as well as a clear idea of what the north-western province of Spain contains can be obtained from a perusal of this very charming book.

"The Card System at the Office." By J. Kaiser. (Published by Author. 5*s*. net.)

Where to find what you want is important to everybody, and to no one less so than the architect. An index of some sort or another is a necessity, and is to be found in most architects' offices, generally in the form of a book. The card system of indexing has many advantages over the older method and a very clear exposition of the system is afforded by Mr. Kaiser's book.

"Sanitation of Public Buildings." By William Paul Gerhard, C.E. (London: Chapman & Hall, Ltd. New York: John Wiley & Sons. $1.50.)

This is an American book by a well-known American author; hence in particular details its information, based on the requirements and customs of the United States, do not accord with British conditions and practice. For example, when the author permits 66 to 68 degrees Fahr. as the maximum temperature for schoolrooms and stipulates that the humidity of the air should be not less than 40 nor more than 60 per cent., it is obvious that his figures are impracticable for Great Britain. As, however, the book rather deals with the first principles than the details of the sanitation of hospitals, theatres, churches, schools, markets, and abattoirs, it is distinctly valuable to the student at an early stage of his career, wherever he may reside. The best feature of the author's treatment of his subject is that he does not attempt to completely deal with any one section, but

Digitized by Google

gives an ample bibliography for those who wish to pursue their studies in any special directions. He, in fact, takes his reader along the first few miles of the road to knowledge and then points out the paths by which may be reached the various provinces of that kingdom.

OUR CONTEMPORARIES FROM OVER-SEAS.

THE *Engineering Record* (New York) describes how a four-storeyed building, 25 feet frontage, 110 feet deep and 50 feet high, in Milwaukee, which leaned 16 inches out of the vertical at top, has been shored and straightened. In its sixth annual contractors' number, our contemporary gives particulars with diagrams of the design and construction of a large concrete retaining wall, 1,665 feet long and 27 feet high, save where defects in the soil required additional depths up to to 5 feet. This wall is situated in Pittsburg. Also in Pittsburg has been executed some remarkable underpinning of the Homœopathic Hospital, whose walls had seriously settled and gone out of plumb. At Galveston, Texas, a tidal wave did so much damage a few years ago that some of the streets were raised several feet, and a description is given of the manner in which St. Patrick's Church and the Broadway school have each been lifted complete, without damage, for a height of 5 feet, and new foundations constructed beneath. In the case of the church, no interference was made in the services during the thirty-five working days occupied in the operations. An interesting article is that on "Artistic and Commercially Practical Surface Finishes for Concrete Work," by Mr. J. H. Chubb, which describes and illustrates how various surface textures may be obtained. Mr. W. M. Christie gives his views and describes his methods, with illustrations, of obtaining depth and detail of photographs of interiors of buildings and engineering structures under the head of "Engineering Photography."

La Construction Moderne has for its principal matter a full set of plans and photographs of the exterior of a lofty block of flats in the Rue de Messine, Paris, a newly constructed street in the wealthy quarter between the Parc Monceau and the Boulevard Haussmann. This building is interesting therefore as an example of the latest thing in Parisian flat-planning, and also as an instance of modern French street architecture. In this case the ornamentation is chiefly of realistically rendered carving in stone of flowers and fruit trees, which meander over the architectural features in more than naturalesque fashion, a method of treatment that we can hardly bring ourselves to admire. The architect is M. Lavirotte.

NOTABILIA.

THE *Irish Builder and Engineer*, to commemorate its jubilee, has issued a special number in which opportunity is taken of the occasion to review what has been done in Ireland during the last fifty years of art work, not only in architecture, but in the other arts. Mr. Robert Elliott treats under the guise of a conversation between the spirits of Truth and Fact on Irish art generally, Dr. Robert Cochrane of archæology, Mr. J. Franklin Fuller of his personal reminiscences, Mr. W. Kaye-Parry of sanitation, and other writers of various aspects of architectural and engineering activity in Ireland during the last half-century. As the text is interspersed with numerous illustrations of buildings erected in Ireland during the period, this jubilee issue becomes a valuable history of Irish architecture from 1859 to 1909.

Garden Design, by John P. White, though virtually a trade catalogue of garden adjuncts in the Japanese manner, contains besides the things that Mr. White is prepared to sell, some charming illustrations of Japanese gardening that make it worthy of notice. Mr. Rowland E. Prothero gives a short sketch of the history of varied fashions in gardening introductory of course to the Japanese "style," but strange to say he does not mention the name of Sir William Chambers, who strongly influenced the eighteenth century taste for Japanese or Chinese forms, and was largely responsible for the introduction of "treillage."

The Future of Glastonbury Abbey has, by the decision of the Advisory Council, constituted according to the trust deed, been settled for the next five years. It has been decided to extend the lease of the former tenant for that period, and in the interval to accumulate funds for the safe restoration of the ruins and the provision of a capital sum for organising special church work.

Correspondence

[The Editor will not be responsible for the opinions expressed by Correspondents.]

Bere Regis Church, Dorset.

Sir,—Can any of your readers tell me whether the notes made by the late G. E. Street, R.A., on the churches he restored (or the contract drawings for the alterations from the work he found), are extant, and if so, in whose possession they are, in cases other than those in which they were deposited with the rectors and churchwardens?

I ask this information with particular reference to Bere Regis Church, in the county of Dorset, which was restored by him in the years 1874-75, and of which an account is now being prepared for the *Architectural and Topographical Record*.

Information as to the existence and ownership of these notes and drawings, or of those of any other churches restored by him will be most gratefully received.—Yours faithfully,

Wilfrid Travers,
General Hon. Sec.
Architectural and Topographical Society.
33 Old Queen Street, Westminster: April 19, 1909.

The Building Exhibition.

Sir,—The present Building Exhibition appears by general consent to be even better than former ones, but why has the collection of illustrations of actual buildings, which formed an important item in last year's Exhibition, been omitted this year? Surely there would have been no difficulty in getting architects to lend drawings and photographs for exhibition. Indeed, the fact that the President of the Institute and a great many architects took part in the opening proceedings shows that architects are very much interested in the Exhibition. It may perhaps be felt that as the architectural room at the Royal Academy will be open in a few days it is hardly necessary to have another collection of architectural designs on view at the same time; but it must be remembered that the Academy does not at present admit photographs, and a really good collection of architectural photographs at Olympia might go a long way towards bringing about an alteration in this matter. In any case there are plenty of working drawings, studies of old buildings and other illustrations that architects could furnish, quite suitable for a Building Exhibition and possessing great interest, but not of such a kind as could be sent to the Academy. It is to be hoped that the custom of former years will be revived in any future exhibition that may be held.—Yours faithfully,

Arthur Keen.

Reading County Offices Competition.

Sir,—Members of the Institute proposing to enter for this competition are requested to communicate with the undersigned before taking any further steps in the matter.

Ian MacAlister,
April 21, 1909. Secretary R.I.B.A.

GENERAL.

We Regret to have to announce the death in his seventieth year of Mr. Edward Potts, F.R.I.B.A., the head of the firm of Potts, Son & Hennings, of Manchester, Bolton and Oldham. The late Mr. Potts was elected a Fellow of the Royal Institute in 1888, and was a recognised expert in the designing of spinning mills, of which he erected a very large number. Amongst his other works were the Manchester Corn Exchange and the Blackpool town hall.

The Architectural Association's Annual Dinner has been postponed from May 5 to May 12 (Wednesday), 7 P.M., at the Georgian Hall, Gaiety Restaurant.

The Birmingham City Council will pave certain thoroughfares at an estimated cost of 16,607*l*. It is proposed to pave Oozells Street with prismatic oak, St. Stephen's Street and Crabtree Road partly with prismatic oak and partly with granite, and Gloucester Street, Bracebridge Street, Derby Street, Essex Street, Icknield Port Road and Western Road with granite.

The Bessemer Gold Medal for the current year has been awarded to M. Pourcel, of Paris, and the presentation will be made at the annual meeting of the Iron and Steel Institute, to be held at the Institution of Civil Engineers, at Westminster, on May 14.

GREEK VASE PAINTING, ILLUSTRATING CONTEST OF ATHENA AND POSEIDON FOR THE SOIL OF ATTICA.

THE WEEK.

We congratulate the University of Sheffield on the opening by the Prince and Princess of Wales of the new library which has been provided by Mr. Edgar Allen and designed by Mr. E. R. Gibbs. Our younger universities recognise architecture as one of the vital interests of modern life, and we trust that they will not forget that research is as much the function of the university as teaching. The space, therefore, in the new library that can be spared for architectural books should not be occupied by cheap and popular books of to-day, but should be devoted to those rare and expensive works that financially are beyond the reach of the average student. To properly study architecture many and costly books are necessary—indeed, the books to which reference is required by every candidate for the qualifying examination of the Royal Institute would cost to buy some 300*l.* to 500*l.* There is another point as to which the greatest care should be given by those who have to select the books for a reference library on architecture. Unimpeachable accuracy is pre-eminently essential for books included in an university library. This, unhappily, is greatly lacking in books on architecture, both old and new, and to enforce a rigid censorship would reduce our library to very small dimensions. The architectural books, therefore, should be divided into two classes—the first, a small one, of reliable books possessing authority as records; the other, far more numerous, of those works that can only be regarded as suggestive.

Mr. Speaight's proposal for the alteration of St. James's Park having been, at any rate for the present, killed by the decision of the First Commissioner of Works, Mr. Eustace Balfour has, in a letter to the *Times*, essayed to drive a few nails into its coffin by a caustic criticism of some of its details, particularly objecting to the scale of the statues that Mr. Speaight proposed and the canal that forms part of the scheme. These are both remediable without destroying the essence of Mr. Speaight's suggestions, and we do not think Mr. Balfour advances the matter very much one way or the other by his criticism. As we have already said, Mr. Harcourt's position is perfectly logical, and his preference for the *status quo* is comprehensible and justifiable. It is of little use, therefore, to cavil at the *minutiæ* of Mr. Speaight's scheme.

The Council of the Royal Academy having requested that notices of the works exhibited shall not appear in the Press until after to-day, our first descriptive article on the contents of the Architectural Room will be given next week. Suffice it to say that the collection is truly representative of present-day architectural work, and that there are some quite remarkable designs included. We like the arrangement adopted this year of grouping together illustrations of similar types of buildings—educational, domestic, municipal, and ecclesiastical.

The Manchester City Council by a large majority has decided to demolish at the earliest opportunity the whole of the unoccupied buildings on the Royal Infirmary site, and thus to put completely out of court any proposal to utilise the old Infirmary buildings for municipal purposes. What is to be done with the site when it is cleared remains for future consideration and decision. The citizens of Manchester may be content to preserve as an open space the million pounds' worth of land, or they may decide to utilise some portion of it for the erection of a fine building. As Mr. Collcutt advised against the retention of the old Infirmary buildings, we are not disposed to cavil at the decision at which the City Council has arrived.

The Irish branch of the Surveyors' Institution at its annual general meeting was much occupied with the Land Bill of the present Session, and passed a resolution expressing their opinion that it would retard, and in many cases prevent, the sales of estates, inasmuch as it would neither encourage the landlords to sell nor tempt the tenants to buy. Although it might be alleged that the gentlemen who passed this resolution were biased in their opinion by the effect the Bill might have upon their position as agents to estates, it must be admitted that they are eminently qualified to pass judgment upon the effect of the Bill now before Parliament.

The competition for designs for buildings suitable for parts of Italy subject to seismic movements, initiated by the Lombardic Co-operative Society for Public Works, with the assistance of the Institute of Engineers and Architects of Milan, has attracted 211 competitors, of whom 40 are from places abroad, including Cairo, Paris, London, Vienna, and Berlin. The schemes are to be exhibited in the Palazzo del Corso Hotel at Milan, and the exhibition will remain open until June 20.

Digitized by Google

STEEL FRAME CONSTRUCTION IN LONDON.

THE London Building Acts do not contemplate the possibility of such a thing as a steel-framed building—that is, one whose loads are borne by a steel skeleton construction, the walls being merely a protective casing to guard the steel frame from weather or fire. The advantages of such a method of construction have already led to the erection in London of steel-framed buildings, notwithstanding the handicap that the present regulations for the thickness of walls place upon a building whose walls are no longer weight-carrying, but relieved of this duty by a steel skeleton.

The Omnibus or "General Powers" Bill of the London County Council for the present Session having reached the Committee stage, it appears to us that this is an appropriate time for considering the provisions of Part V., which deals with the amendment of London Building Acts, with the view of removing the archaic restrictions that now hamper the development of the use of steel in architectural work.

Several professional societies and associations are opposing the Bill, but as our readers are probably aware, it is only by technically "opposing" a Bill that one can be heard, if one has a friendly suggestion to make for what one thinks may be an improvement. It is scarcely conceivable that any body representative of either the engineering or the architectural profession could object *in toto* and as a matter of principle to any amendment of the London Building Acts that is intended to facilitate the more extended use of steel, whether in the form of steel-skeleton construction or of reinforced concrete.

The details of the construction of steel-framed buildings that are included in the provisions of the Bill are so intensely technical that there is ample room for legitimate difference of opinion amongst experts as to these details, and so far the professional societies may be held justified in "opposing" the Bill *primâ facie*—for example, it might very well be argued that the stipulation that no steel pillar shall have an unsupported length of more than thirty-five times its least width does not make sufficient allowance for the superiority of mild steel over cast iron in pillars of many diameters in height.

Speaking generally, the technical details of the construction of steel-framed buildings have been admirably considered in the drafting of the Bill, and we might very well recommend them as a text-book on the subject to young engineering and architectural students. But notwithstanding this general commendation, there are points that are fairly open to discussion.

It is proposed to be enacted that "The compression flange of every girder shall be secured against buckling whenever the length of the girder exceeds thirty times the width of the flange." Herein is a wise recognition of the fact that girders usually fail by buckling of the compression flange, a recognition that evidences practical experience brought to the assistance of the draftsman of the Bill. But how is the security against buckling to be provided? Are stiffeners connoted or may concrete fulfil the function, as it is relied upon to do in one of the latest forms of fire-resisting floor placed on the market?

Again, "All party walls shall be of the thicknesses prescribed by the principal Acts (*i.e.*, the London Building Acts, 1894 to 1908) and may be built in lime mortar." This is a knotty point. On the one hand it may be advanced that a steel-skeleton building should have a complete skeleton, and that its metal framework system should embrace party wall as well as external wall and internal supports. On the other hand, it may be argued that a party wall, being the joint property of two owners, the man who wants to build a steel-frame building on one side should not be allowed to prejudice his neighbour, who does not wish to do so on the other.

It is prescribed that the metal-work of skeleton framing shall be coated with boiled oil, tar, or paint, save that when encased in concrete, Portland cement wash may be used instead. Here, we think, a little more elasticity is desirable, so that, in the event of improved methods of protecting steel being invented or discovered, it may not be necessary to amend an Act of Parliament before they can be used in London. Already there is a process by which steel-work can be coated with tin.

The Bill makes a distinction between the "dead load" and the "superimposed load" that the skeleton frame of a building has to carry. Briefly, the former is the weight of the building, the latter of whatever may be placed in or upon the building, including wind-pressure.

The loads to be estimated for floors are specified, and though less than are given in some text-books, are more than actual experience proves to be usual, so that they are on the safe side.

For roofs of a pitch of twenty degrees or less, the superimposed load is to be estimated at fifty-six pounds per square foot, measured on a horizontal plane. For roofs of a pitch of more than twenty degrees, the superimposed load is to be estimated at twenty-eight pounds per square foot of sloping surface. Is this enough for steep roofs? At least it seems arbitrary that there should be so much difference between roofs of twenty and twenty-one degrees. Would it not be better to make the superimposed load on roofs vary with the cosine of the angle?

Objection has been taken to the inclusion of interior frame-structure amongst the construction to be regulated by the Bill; but we hardly see how this is to be disassociated from the framework of the external walls. If the latter is to be regarded separately, cognisance cannot be taken of the support that the internal framework affords, for the adequacy or otherwise of that support is dependent on the sufficiency of the internal work. Again, the sole *raison d'être* of any legislative supervision or enactment is the public safety; and of what use is it to make the external walls safe if the internal framework of floors and their supports is permitted to be possibly dangerous?

Another objection that has been raised is that architects and their clients should not be put to the expense of supplying copies of drawings and calculations to the district surveyor. But when a steel-frame building is to be erected someone has to make drawings and calculations for it, and the mere cost of an additional copy of these is surely not a serious matter.

We have our own objection to make. We doubt if the district surveyor is the best authority to determine whether the design of a steel-frame building is safe. Doubtless some of our district surveyors are fully competent to perform the duty, but the examination by which they have obtained their certificates of competency has not, up to the present, been such as to test their ability and knowledge in this direction. We know that some of the present district surveyors would rather not be saddled with the labour and responsibility of examining the design and supervising the construction of steel-framed buildings, and that they do not regard the increased fees as adequate for the extra work involved. We should, therefore, suggest that the County Council should take the place of the district surveyor in the Bill, and then a special department of experts under the engineer or architect of the Council would be created, far more able to check calculations and designs of steel-framed structures. The appeal from district surveyor to the Council proposed by the Bill should then become appeal from the County Council to the Tribunal of Appeal, who would employ their own expert to advise them.

COMPETITION FOR EXTENSION OF GRIMSBY TOWN HALL.

THIS will not be an easy competition to tackle, and the conditions do not at present make everything quite clear. The matter is still further complicated by the fact that "a preliminary scheme has been prepared by the Borough Engineer on the suggestion of Alderman Sir GEORGE DOUGHTY, M.P., and a copy of this is furnished to competitors as an indication of what is desired." Competitors are not bound to follow this scheme, but it has

Digitized by Google

evidently formed the basis on which the Corporation have decided the amount they wish to spend, and one of the conditions is that "architects submitting designs must guarantee that their scheme can be carried out exclusive of furnishing, electric light, and architect's charges for not more than 26,000*l*."

Under the preliminary scheme parts of the existing buildings are retained, and we think insufficient allowance has been made for the cost of supporting and altering the old work. For example, it is proposed to retain the council-chamber on the first floor, which at present has its walls carried by solid walls on the ground floor. In the suggested scheme, the end walls and half the back wall only have their old supports, and these undergo alterations; so, as the council-chamber cannot be supposed to possess the properties of MAHOMET'S coffin, there is a pretty problem to solve in its temporary and permanent support. Of course it can be done, but it will cost money.

In brief, the extension consists of an enlargement of the present assembly hall, the provision of office accommodation for municipal officials, and the expansion of the Police Court into three separate Courts—Police, County, and Registrar—with increased cell accommodation, &c.

The way in which the preliminary scheme has been evolved may be gathered from the opening paragraphs of the "outline of scheme." The present assembly room (on the first floor) is about 94 feet by 40 feet 6 inches. "It is proposed to bring forward the front wall of the building about 19 feet, to extend the end eastwards about 36 feet, and the other end westward about 21 feet, thus making a great hall about 130 feet by 59 feet 6 inches." Thus it is evident that the "extended" assembly room will be very much like the Irishman's coat in the amount of the present building that it incorporates.

There is another aspect in which the preliminary scheme hampers competitors. This scheme embodies faults that we should regard as fatal if we were assessing the plans in a competition. For example, the Town Clerk's department is a clear space 54 feet long by 27 feet wide, lit at one end from the open, and at the other from an area 9 feet 6 inches wide, partly covered on the first floor. The smaller assembly room, "capable of being used for exhibiting loan collections of pictures," and therefore presumably to be visited by ladies and other persons of refined tastes, is approached by a grand staircase, to reach which visitors must pass through the public entrance and general waiting-room for the Police, County, and Registrar's Courts. The existing premises are a regular rabbit-warren, and the plan of the preliminary scheme partakes very much of the same character. Any plan a competitor may submit that would be more satisfactory than the one suggested would almost inevitably entail greater cost.

It seems to us that there are only two courses open to those architects who propose to take part in this competition—either to adopt the by no means excellent plan of the preliminary scheme and design elevations to it, or to spend two or three days at Grimsby in order to study how most economically and advantageously the present buildings can be utilised. This is so much a matter of opinion that we do not see that competitors who hope to win can avoid the necessity of a personal visit by the furnishing of any information that we can give them.

The plans to be submitted include to one-eighth scale, plan of each floor including mezzanines; north and west elevations, tinted; sections (undefined number) and a perspective "if the competitor so desires." These are to be sent in on or before July 30 next.

"It is intended to appoint an architect of eminence to advise the Corporation as to the suitability of any of the designs for its purpose." This gentleman, when appointed, will be assisted by the Borough Engineer, and the premiums are offered for the designs "recommended by the assessors." "It is intended to appoint the architect of one of the premiated designs to carry out the work."

COMPETITION FOR SECONDARY SCHOOL AT WHITBY.

THIS school is to provide accommodation for 150 students, with provision for extension to take another 50. The amount to be expended is not to exceed 45*l*. per child accommodated. It is the "intention" of the Education Committee of the North Riding of Yorkshire County Council to entrust the work to the author of the design placed first by the assessor, Mr. PAUL WATERHOUSE, M.A., and further to give an honorarium of twenty and ten guineas respectively to the authors of the designs placed second and third by the assessor. The usual commission of 5 per cent. is to include travelling and out-of-pocket expenses.

The school is to be a mixed one—that is, the classes will be mixed, but separate cloak-room accommodation is required for the sexes. The special rooms required, in addition to the class-rooms, are not extravagant, so that there should be no difficulty in designing a school with the necessary desiderata for the sum allowed. The site is ample, and presents no special difficulty, except that a portion falls away at a steep slope. Drawings are to be sent in not later than July 17 next, and are to include block plan to scale of 20 feet to the inch, plan of each floor, not less than two sections, and four elevations to one-eighth scale. No perspective allowed.

COMPETITION FOR COUNTY OFFICES AT READING, BERKS.

AS our readers will have gathered from the letter of Mr. IAN MACALISTER in our last issue, all is not well with this competition. In our first article on the subject, we pointed out that the conditions gave the County Council power to ignore the assessor's award except as regards payment of premiums. To this, very rightly, the Council of the Royal Institute has objected, and a circular letter to competitors has been sent out this week by the County Surveyor intimating that "the assessor appointed has been compelled to resign," and that the competition is "suspended for the time being," "pending the decision of the County Council, which cannot be made known before May 8."

THE SOCIETY OF ARCHITECTS' ANNUAL DINNER.

A GATHERING of nearly 200 signalised the twenty-fifth annual dinner of the Society of Architects at the Trocadero Restaurant on Friday, April 23.

The chair was occupied by the president, Mr. Geo. E. Bond, J.P., and amongst those present were Mr. Ernest H. Lamb, C.M.G., M.P., J.P., Mr. T. B. Silcock, M.P., His Honour Judge Rentoul, Mr. A. A. Hudson (president of the Tribunal of Appeal), Mr. Edward White, J.P. (vice-chairman, London County Council), Mr. W. E. Riley, F.R.I.B.A. (architect, London County Council), Mr. G. L. Gomme, F.S.A. (clerk, London County Council), Mr. E. B. Barnard, M.P., J.P. (chairman of the Metropolitan Water Board), Mr. Walter Cave (president of the Architectural Association), Councillor Willis (mayor of Rochester), Mr. Alfred Neale (master of the Tylers and Bricklayers' Company), Mr. Murray Janes, C.C. (master of the Painters Stainers' Company), Mr. Maurice H. Pocock (master of the Carpenters' Company), Mr. Howard Martin, F.S.I. (president of the Surveyors' Institution), Mr. E. Purnell Hooley, M.Inst.C.E. (president of the Association of Municipal and County Engineers), Mr. W. S. Wallis (president of the Institute of Builders), Mr. F. G. Rice (president of the Master Builders' Association), Alderman A. J. Hopkins (mayor of Marylebone), Councillor Archibald Dawnay (mayor of Wandsworth), Mr. Edwin O. Sachs, F.R.S. Ed. (chairman of the British Fire Prevention Committee), the Mayor of Chatham, Alderman H. F. Whyman, C.C., Alderman J. R. Featherby, J.P., Alderman W. D. Driver, J.P., Alderman C. E. Skinner, Mr. Charles Tuff, J.P., Mr. R. D. Batchelor, J.P., Mr. William Banks, A.M.Inst.C.E. (city surveyor, Rochester), Mr. Charles Day (borough surveyor, Chatham), Mr. R. Geo. Bare, Mr. Ellis Marsland (hon. sec.), Mr. Wontner C. Smith (hon. sec. A.A.), Mr. Edwin J.

Lidiard James, F.R.I.B.A.

Mr. GEORGE E. BOND, J.P., President of the Society of Architects, having proposed "His Majesty the King" and "Her Majesty Queen Alexandra, their Royal Highnesses the Prince and Princess of Wales and the other members of the Royal Family," his Honour Judge RENTOUL proposed "The Houses of Parliament." He said that he had been preparing himself during four and a half hours for this particular dinner, having been engaged in trying a case between two architects. The question at issue was what was the proper qualifying fee to pay a professional witness for giving evidence necessary to win the case. Various distinguished architects were called. After a lengthy hearing his Honour asked if he might be allowed to send the case to a professional friend, for though he felt more or less able to decide as to the veracity of lawyers he could not do so as to architects. However both sides agreed to leave the case in his hands, and he gave his decision in a very halting manner, not being at all certain whether he was right or wrong. In alluding to the House of Lords he felt he was treading on dangerous ground, for it was so much a Liberal power. Since 1830, of the peerages created 243 were by a Liberal Government and only 179 by a Conservative; it was therefore a very Liberal House. As for the House of Commons, one of the saddest facts of his history was that he did not still belong to it. It was ridiculous nonsense to talk about political honesty or political dishonesty, for there was just as much honesty on one side as on the other. They were merely fighting their cause from different points of view. It would be wrong if he was to condemn the Liberals because he happened to profess another faith. They had just as much right to be wrong as he had to be right. The House of Commons was always ready to extend a hearing to a man with a real message.

Mr. ERNEST H. LAMB, C.M.G., M.P., J.P., in responding, remarked that he was set a somewhat difficult task in following Judge Rentoul. A Bill for the registration of architects had been introduced into the House of Commons. It was not his place to offer advice, but he should like to say that while the House was anxious to do its best with the Bills put before them, it was obvious that the opinion outside must be unanimous. The time had come, now that the Bill has been read, for architects to decide whether it is a profession or an art. If a profession, it should have registration; if an art, it should be left alone. Before the Bill could pass through the House an extended inquiry was necessary; it might prove that there was not that unanimous desire which was essential for success. When doctors disagree, who shall decide? It was always very necessary that those who promote private Bills should come agreed among themselves. Sometimes the mistake is made of putting a Bill on too high a ground, where it cannot be sustained. He was quite convinced that if the profession could come to a unanimous decision they would not find the House of Commons backward.

Mr. GEORGE E. BOND, J.P., the President, in reply to the toast of "The Society of Architects," said that the way in which the toast had been received was an encouragement for him to feel that the indulgence of those present would be freely extended to him while he endeavoured to justify the position the Society of Architects had taken up with regard to registration, a subject with which the name of the Society had been identified. Twenty-two years ago the Society pledged itself to promote a Bill having for its main object a statutory test for those who desired to become architects. The Bill was thrown out because of a clause which included engineers and surveyors. That was remedied, but nevertheless the Bill has never since obtained a hearing. The Society has ever since endeavoured to redeem its pledge, and it will never relax until that Bill or another based on the same principles is definitely placed upon the Statute Book. Their contention was that it would prove an advantage to the building public equally with the profession. In the first place they endeavoured to improve the status of the architect. They wished to raise the general professional practice by better preparing the architect for the multifarious duties involved in his whole work. They desired to protect the future from those who without a single qualification styled themselves architects, and practised as such—men who just keep within the common law, though drawing remuneration undreamt of by their client. Architecture demands a whole-souled devotion from its followers, and as a consequence its practice ought to be strictly confined to persons systematically educated to perform the duties involved in an artistic and practical manner, and also to appreciate the seriousness of their great responsibilities. The dominating principle of their Bill was the establishment of a scheme of compulsory examination to be passed by all before commencing practice. This would automatically prevent any growth of the nondescript class. The qualifying examinations would prove a valuable inducement for study among students and enable them to turn to account the opportunities offered in spare time. At the present moment many architectural students neglected those opportunities, contenting themselves with the more or less satisfactory performance of the routine duties in the office during the three or four years of their pupilage. Then they go for a year or two as junior assistants. When the time comes for them to set up in independent practice they are inadequately equipped and have to depend chiefly on the kindly help of the builder. The presence of this class is as bad for architecture as for the public. The health, comfort and convenience of the community, its great financial interests in building operations, and all the conscious or unconscious poetry derived from the contemplation of beautiful things are dependent upon the artistic sensitiveness, ability and rectitude of the general body of architects throughout the country. No other profession demands such varied gifts or diverse knowledge, or is saddled with greater responsibilities. Yet it is possible for a chimney-sweep to put out a brass plate and practise as an architect. The public have no means of differentiating between the qualified and the unqualified. Perhaps these examinations would not do everything, but the study and special preparation involved would be of infinite value to students. The main opposition to the Bill might be fairly described as a paradox, for it maintains that artistic qualification cannot be tested. At the present moment the majority of these opponents belong to a body which for many years has made compulsory these very tests. Yet they declare that the Society's schemes would tend to reduce the art of architecture to a dead level of mediocrity. It might be suggested to these people that they ought not to confuse the high artistic ideals of the few with the general practice throughout the country. And they should be asked if they at the present moment are satisfied that existing conditions are conducive to the best and highest interests of architecture as an art? They should not forget that their predecessors contented themselves for more than a century in observing

Digitized by Google

certain rigid rules of art. It should be fully realised that architecture is essentially a constructional art, and in its very highest form springs inevitably from the working of true genius with sound practical knowledge, in the best materials at its command, with the deepest sincerity and the highest possible aim; and a real work of architectural art lives with us to-day, not by virtue of its beauty only, but to an equal extent by its truth in construction and its practical utility to serve its purpose. Each one unites beauty, strength and practical utility. Consequently there can be no hesitation in saying that the upward flight of true architectural genius will be assisted by such practical study as will enable them to pass successfully the suggested examination. The fact still remains, though we may affect to believe otherwise, that an architect fully qualified to do justice to his client must be not only an artist, but a scientist and a practical man of business. But for years a cloud of false sentiment has hung over the profession, to its great detriment. The membership of the Society is now considerably over a thousand, and it is still growing. There is no desire to enter into rivalry with any other body. Their only aim was to advance the art and profession of architecture and its best traditions. That the vast majority of architects are in agreement with the Society was suggested by the highly satisfactory results of the plébiscite carried out by the *Builder*. Five thousand copies were distributed, pointing out the advantages and disadvantages of registration, together with a postcard asking for a reply. Of the answers received, 2,113 were in favour and 264 against registration. That is to say, eight were in favour to every one against. Therefore the vast majority of architects throughout the country were in agreement. The remedy for the existing state of affairs lay in the Bill which has been before the public for twenty-one years. The time has come for a cessation of petty policy. All sections should send fully accredited representatives to discuss the matters at issue and to unanimously agree upon the Bill to send before Parliament. The difficulty might be entirely obviated by a friendly discussion among gentlemen.

Mr. Walter Cave, President of the Architectural Association, proposed "The Local Authorities." He said that he had experience of one or two local authorities, but that many others had come across them in a larger capacity than he had. There was a very common tendency to forget, in dealing with local authorities, that it was an Act of Parliament that they have to carry out. They are often approached in a wrong manner and considered as a nuisance. As people grow older they perceive that these Acts are in nearly every case of the utmost value, and the longer they live the more they appreciate this. The very fact that the local authority undertakes these onerous duties should never be forgotten. The law is administered here in a way that is unequalled in any other country. We are proud of our local authorities and the high standard of official life.

Mr. Edward White, J.P., Vice-Chairman of the London County Council, in response, said that as a builder himself he knew that the building trades would welcome registration.

The President gave the toast of "The Visitors," to which Mr. Leavey responded.

During the evening an entertaining musical programme was gone through, which concluded with the company singing "Auld Lang Syne."

THE SOCIETY OF ARCHITECTS.

A MEETING of the Society of Architects was held on Thursday, April 22, Mr. Ellis Marsland, hon. secretary, presiding.

Mr. A. A. Hudson was elected an honorary member and the following were also elected as members:—Messrs. Walter Andrew, Geo. Kenshole, G. S. Smith, Ch. R. Tudor, T. S. Vickery and Richard Willock. For studentship:—Messrs. F. M. Cashmore, L. L. Corkill, G. E. Hunter, W. J. McClure, B. J. Mendham, F. D. Sowerby, H. E. Willmets, G. Matthew Willis, W. Bradley, H. E. Matthews, Frank Brown, G. L. Evans, George Revitt, W. Macgregor Gibson and Horace Fyvie.

The Dangers of Breeze Concrete.

Mr. D. B. Butler, A.M.Inst.C.E., F.C.S., read a paper, illustrated by lantern views, in the course of which he said:—

During the past few years the author has met with increasingly numerous instances of failure of concrete composed of Portland cement and breeze, failures as a general rule caused by the expansion of the mass, resulting in more or less serious consequences to the structure of which it formed part. These failures have generally occurred where the concrete has been used to form flat roofs, or fireproof concrete floors, on the well-known embedded rolled joist system of construction; in some instances the expansion has been but slight, though noticeable; in others it has been sufficient to push out the brickwork walls, causing serious bulging and thus endangering the safety of the whole structure; while in one extreme case a flat roof composed of breeze concrete not only expanded sufficiently to push out the parapet walls and seriously endanger the stability of the structure, but the internal disruption set up within the mass was sufficient, owing to incipient disintegration, to cause it to become buckled and distorted and thoroughly rotten.

Careful investigation of some of the foregoing cases of failure justified the opinion that the mischief lay with the cement, but in many instances the most careful and searching investigation, both chemical and physical, disclosed nothing sufficiently definite in character to enable the investigator to lay his finger with positive certainty on the cause of the trouble. In nearly all the samples of so-called "breeze" concrete a very considerable quantity of material other than pure coke was noticeable in the aggregate, such as clinkers, stones, shale, ashes, &c., together with in some instances a noticeable amount of coal. It may be remarked in passing, that judging from the quality of the "breeze" which may daily be seen being delivered to buildings in the course of erection, presumably for incorporation in fireproof floors, &c., many a clerk of works must be imbued with a pleasing and childlike faith in the ability of Portland cement to stick together any kind of rubbish; it appears to be an established belief with some cement users that to produce a good concrete it is only necessary to have good cement and that any dustbin refuse or other rubbish will serve for aggregate, and it is not until failure occurs that they realise that they have been asking and expecting the cementing medium to perform impossibilities.

It is questionable whether on account of its combustible nature, pure breeze, i.e., fine coke, is desirable as a fireproof material; an instance has recently been brought to the author's notice in which a breeze concrete enthusiast used that material for a boiler setting, which eventually took fire and gradually smouldered away, with results that can be better imagined than described. Whatever may be the disadvantages of other extraneous material found in breeze, it will be readily understood that coal is not a desirable constituent for concrete; in the first place on account of its smooth shiny surface, the adherence of the cement would be extremely poor; in the second place, it is worse than useless as a fireproof material, on account of its tendency to decompose on heating. The question arose, however, whether apart from being undesirable for the reasons aforesaid, either coke breeze or coal was in any way dangerous as being likely to cause expansion of the concrete.

The first experiment was of a somewhat rough and ready nature and was made with coal. An ordinary bituminous house coal was crushed and sifted to about the fineness of standard sand, i.e., passed through a $\frac{1}{10}$-inch sieve and retained on a $\frac{1}{30}$-inch; with this coal a three to one mortar was made, and two small two-ounce glass bottles filled with the mixture; one bottle was filled quite full, and the other was filled to within a quarter of an inch of the top and sealed down with a paste of neat cement, the object of the sealing being to ascertain whether the imprisonment of any hydrocarbons set free from the coal would have any bursting effect. For comparative purposes a similar bottle was also filled with a paste of neat cement and three to one mortar of standard sand. Sixteen cements of various qualities and different origin were tried, some being sound when tested for expansion by the Faija test and the Le Chatelier boiling test, and some otherwise; the samples were those which passed through the author's hands for testing in the usual course, and were not specially chosen except for the purpose of obtaining as varied a selection as possible. English, German, Belgian, and Swedish cements were represented, and the results of these experiments were as per following table:—

REFERENCES:—C 28 D = Bottle cracked after 28 days. B 28 D = Bottle burst off after 28 days. NB 12 MO = Bottle not burst off at 12 months.

It will be observed that the whole of the bottles eventually cracked, with the exception of No. 12 filled with standard sand-cement mortar. But while those filled with the coal mortar generally cracked within two or three days, and with a very few exceptions continued to expand until the bottles burst away into several pieces, those filled with the neat cement and the sand mortar frequently did not develop any cracks whatever till several months, and it was the exception rather than the rule for them to continue expanding sufficiently to burst the bottle. A very good example of this is afforded by cement sample No. 16. It will be observed that both the neat cement and sand-cement mortar bottles remain perfectly sound after eleven months, and then only develop very minute cracks, whereas the coal-mortar bottle was cracked in twelve days, and burst right off in forty-two days. This suggests that the cause of the cracking after such protracted periods might be due to unequal expansion of the glass and the mortars at varying temperature; according to "Ganot's Physics" the co-efficient of linear expansion between 1° and 100° C. of glass is 0.000008613, and wrought iron (which is said to be the same as cement) is 0.000012204, or nearly 50 per cent. higher. Though, as before stated, the bottle test is only a rough one, it serves to show that coal develops dangerously expansive properties when mixed with cement, but since there is no clearly marked difference between those bottles sealed down with neat cement and those unsealed, it does not favour the theory that the expansion is in any way due to the evolution of gas within the mortar.

The next step was to test samples of so-called "breeze." of various origin, to ascertain if the coal sometimes present (probably partially burned) was unsafe, and also if there were other constituents present which might prove detrimental. Several samples of good breeze were procured; also some which the author was assured by the breeze merchant would never be sanctioned by a good clerk of works; the constituents of the latter, however, did not differ materially from the ingredients to be found in breeze concrete from many important constructive works.

With all the samples tested the general method was to separate them into their several fractions or constituents, so as to be able to identify, if possible, the cause of the expansion, if any. Each sample was therefore carefully separated out as follows:—

1. The fine material passing through a -inch sieve.
2. The fine material passing through a ¼-inch sieve, but retained on a -inch sieve.
3. The coarse material retained on a ¼-inch sieve; this was picked over by hand and separated out into its various constituents, such as clinkers, coal, coke, &c.

An "average" sample was also prepared, being 1, 2 and 3 mixed together in their proper proportions.

The variety of materials in some of the samples of so-called "breeze" was considerable, and in addition to coal, coke and clinkers, rubbish of all sorts was present, such as bits of steel saw, nails, brass and iron turnings, and other metal fragments, broken pottery, &c.; in fact, savouring rather of the rubbish usually found in the dustbin than of coke breeze proper. The percentage of each fraction was carefully recorded, and as a convenient size for making into

Digitized by Google

mortar for testing purposes, was broken up to pass a $\frac{1}{10}$-inch sieve.

Two cements of previously ascertained stability of volume were used for the experiments:—

A, produced from the well-known lias formation near Rugby.

B, produced from chalk marl deposits and clay in the Midland Counties.

The bottle test, previously described as having been carried out with the coal mortars, was somewhat crude, and also qualitative rather than quantitative; moreover, as previously pointed out, it might conceivably be influenced by the difference between the co-efficient of expansion of the glass and of the mortars at different temperatures. In order, therefore, to render them more accurate and of a quantitative nature, the subsequent experiments with coke breeze mortars were made with prisms or rectangular bars 100 millimetres long and 22 millimetres by 22 millimetres cross section, the expansion and contraction of which were accurately measured in the Bauschinger micrometer calliper apparatus.

Cement and Standard Sand.—Eight bars or prisms were made with each kind of cement, four being made with neat cement and four with 3 to 1 standard sand-cement mortar. Two of each series were kept entirely in air and two placed in water after twenty-four hours, and kept therein during the three months with which this record deals. Each bar was measured after one day, seven days, twenty-eight days and three months.

Breeze Sample No. 1.—Described as "fine pan breeze"; it consisted mainly of clinker and coke, with traces only of coal. Separated out as previously described, about 32 per cent. passed through a $\frac{1}{10}$-inch sieve and 35 per cent. through a $\frac{1}{4}$-inch sieve. Of the remaining 33 per cent. about 22 per cent. was clinkers, and 11 per cent. coke with .08 per cent. coal. Each of these fractions, after being broken up to pass a $\frac{1}{10}$-inch sieve, was made into prisms or bars with the two different kinds of cement, two bars of each being left in air and two placed in water after twenty-four hours, and measured after one day, seven days, twenty-eight days and three months. The expansion, though measurable, was practically negligible in each case, being about 0.1 per cent.; the air bars, as with the standard sand bars, generally showed slight contraction.

The two cements give identical resulfs with each fraction or portion of the breeze, and the same remark will be found as a general rule to apply throughout to the whole of the subsequent experiments, whether the expansion be great or small.

Breeze Sample No. 2.—Described as "coarse pan breeze." This sample consisted of coke and clinker only, in pieces averaging about 2 inches diameter, the proportions being about 35 per cent. of clinker to 65 per cent. of coke. Treated in an exactly similar manner to No. 1, the results were likewise practically negative.

(To be concluded.)

QUEEN'S COLLEGE, OXFORD.*

By John R. Magrath, D.D., Provost.

(*Continued from page* 255.)

Provost Smith was at some trouble in estimating the amount of Lancaster's benefactions to the College. He took the sums evidenced by the Building Account Book to have been spent during his time, and deducted therefrom the benefactions received and the proceeds of the timber cut down and sold for the purpose, and concluded that Lancaster must have given of his own not less than 4,000*l.*, besides the 1,000*l.* which he bequeathed to the College at his decease. At Lancaster's death the new hall and chapel, begun in 1713, were approaching completion, but though Lancaster had spent most of his savings and had been backed by the liberality of several old members and friends of the College, there was a good deal of financial perplexity and anxiety for the future. The North Quadrangle was still unfinished, the south and east sides of the South Quadrangle were untouched, and not all the building already accomplished was paid for.

It took the thirteen years of Gibson's provostship, the further assistance of others who had been of the College, and the contribution of all that the members of the foundation could spare out of their own subsistence, to finish the north court and pay the arrears of the cost of what Lancaster had carried out. At the end of February 1718-9 Hearne reports that a part of Queen's College building butting against Peter-in-the-East Churchyard began to be pulled down. These must have been the old buildings just south of Sir Joseph Williamson's buildings which were retained in the new structure. In May 1719 the old chapel was begun to be pulled down. Till the new chapel was consecrated the College prayers were held in the chapel of Edmund Hall at six in the morning and five in the evening, so as not to clash with the Hall prayers. The service was soon transferred to St. Peter's Church, "under pretence," as Hearne says, "that Edmund Hall chapel will not hold them, and yet 'twill hold about 150, if matters are well ordered, whereas they have little more than three score at a time at prayers."

The new chapel was consecrated on Sunday, November 1, 1719, by Sir William Dawes, Bart., Archbishop of York and visitor of the College. He was received at the College gate, where a speech "was spoke to him" by Mr. Fletcher, one of the Fellows. Hearne objected to Fletcher as very dull and to his speech as "poor canting stuff, and y^t he spoke it in a whining manner, as if he had been a Presbyterian," but then Fletcher had been intruded into the sub-librarian's place at the Bodleian ("I having never resigned it"). The sermon at the consecration was preached by the Provost, and the dinner that followed "very great and," according to Hearne, "very extravagant."

The thirteen years of Gibson's rule saw the hall and chapel finished, the chapel consecrated, the north court entirely finished, and the College out of debt. To secure these objects an appeal, illustrated with cuts of the College as it was to be, was widely circulated, contributions came in, and the members of the foundation gave annually themselves all that could possibly be spared out of their own subsistence. The hall is 60 feet long by 30 feet wide; the chapel, continued to the eastward beyond the north-east corner of the front quadrangle and ending in an apse, has a total length of 100 feet.

The modifications in Sir Joseph Williamson's building involved in its incorporation in the new work included a recasting of the eastern face and the doubling of the depth of the building. At the foot of the stairs in the present staircases, Nos. 3 and 4, the old doorways from the quadrangle can be discerned. Staircase No. 5 owes the irregularity of the shape of its rooms and their unusual size to the difficulties of filling up a corner incidentally created by the meeting of two lines of buildings independently erected. Though the rooms are not such as would have been specially devised for this purpose, the difficulty has been overcome with a good deal of skill. A comparison of Loggan's picture with the actual eastern face of the back quadrangle will show that the architectural features have been quite altered. Some notion of the old arrangement may be formed from the present north face of the same building, where an empty niche with Sir Joseph's crest carved under it preserves a feature of the old eastern front.

The completion of the front quadrangle was left for Smith's provostship. Before the year of his election was out, an account was drawn up of "The Present State of the New Buildings of Queen's College in Oxford." Two hundred copies of the "State," as it was called, were printed off, and six of the fourteen cuts which Burghers had engraved for Gibson's appeal were added to each copy. Among the earliest of those to whom copies were sent were Lord Cardigan and Lord James Beauclerk, afterwards Bishop of Hereford. It was estimated that 5,000*l.* in all would be wanted for the work—3,600*l.* for the east wing, 800*l.* for the new gate and cloister, and 600*l.* for the purchase of such of the tenements on the High Street front as did not already belong to the College. No time was lost in making application to Queen Caroline for a share of her Royal bounty, and so successful was the petition drafted by Smith and presented to the Queen in the following January that not only was 1,000*l.*

Digitized by Google

given in four instalments between November 1733 and November 1734, but a further 1,000*l.* was promised, which, as the College Benefactors' Book records, "adhuc nobis insoluta, sed non insperata manet." A further circular was prepared by SMITH and sent "to the worthy Gentlemen of the two Northern Counties to which our Foundation is peculiarly appropriated." How widely this was circulated does not appear, but it does not seem to have produced much result. The actual contributions came mainly from those who were or had been members of the foundation. Five hundred pounds also was gained from the accumulations of the BRIDGMAN fund, which was secured to the College about this time by the activity of the indefatigable Provost.

The statue of Queen CAROLINE which stands over the main gate was made by CHEERE after a model which had been seen and approved by the Hon. GEORGE CLARK, Esq., and Sir JAMES THORNHILL. It was to have been 6 feet high, and CHEERE was to be paid for it 120*l.*, but as it was made 3 or 4 inches higher CHEERE received five guineas extra. The agreement was made May 30, 1734, and the statue was to be finished by the end of May 1735. The cost of the cloister with the modified cupola was estimated by TOWNSEND at 1,045*l.* The oak-work of the door closing the gate was estimated for by a man named FRANKLIN at 45*l.* 16*s.* 6*d.*, and came with some extras to 10*l.* 3*s.* 2*d.* more.

In a letter from a gentleman in Oxford to his friend in London, printed in the *Daily Post*, February 12, 1736, the "open temple" over the main gate in High Street is said to be "built after the design of Mr. HAWKESMOOR," and the statue of Queen CAROLINE "made by the ingenious Mr. CHEER, of Westminster." It appears from a letter written to Provost SMITH by WILLIAM TOWNSEND, the builder of the screen in front of the College, dated August 28, 1733, that he "made some alterations in the design of the Cupola" involving the "taking of the Coping and Fascia off that part of the Cloyster which is already done." HENRY CHEERE (knighted 1760) was also paid 135*l.* for making the three statues of Portland stone on the pediment of the east wing of the College representing Law, Physick, and Poetry, by agreement dated July 4, 1734. The statues were to be cut out of the solid stone, and not pieced as those at the end of the west wing. The latter seem to have been replaced by more substantial, if less artistic, ones early in the nineteenth century. The room above the porter's lodge was probably the last addition to the College buildings. The date of the order for its building was December 1, 1758.

To the new chapel were transferred from the old one some Perpendicular glass, some figures of bishops which appear from the date, 1518, upon them to have been placed by LANGTON in his ante-chapel, and a number of large glass pictures by the family of VAN LING, who had been glassmakers in St. Clement's from the days of CHARLES I., and whose degenerate representative, JOSHUA PRICE, is accountable for the east window and the little figures of Apostles in some of the demilunes at the tops of the windows. The fine brass, also transferred, by BURROUGHS, 1661, had been bought with a bequest left by JOHN PETTY, one of the Fellows intruded by the Parliamentary Commissioners, who had learnt in his short life to love the College to which he had been transferred from Balliol. The organ was designed by LEIGHTON GEORGE HAYNE, D.Mus., who was organist from 1858 to 1866. The windows in the hall were executed by Messrs. POWELL, of Whitefriars, from designs by Mr. REGINALD BLOMFIELD. The College owes them to the liberality of GEORGE AUGUSTUS SIMCOX, recently a Fellow of the College. The western wing of the front quadrangle has been destroyed by two fires, the first in 1778 destroying the Provost's house and the staircase to the south of it, and the second in 1887 the staircase fronting on the High Street. The front of the chapel and hall towards the southern quadrangle were refaced in 1864, and other portions of the building have had to be dealt with from time to time, but no new feature has been introduced to affect its general character, and the College is as it was when the cupola was finished in 1734.

The architectural reputation of the College has varied according to the fashions of the time. In the eighteenth century it was given a first place among the architectural glories of Oxford. The Gothic and mediæval revival altered all this, and even the last edition of MURRAY'S "Guide" talks of its debased style. We are apparently becoming again more cosmopolitan and able to appreciate various styles of excellence. The front of the College forms, even in the judgment of the Goths, "a striking feature in the High Street."

LIVING ARCHITECTS.—NO. 6, MR. LEONARD STOKES, V.P.R.I.B.A.

MR. LEONARD A. S. STOKES was the Pugin student in 1880, and President of the Architectural Association for two sessions, 1889-90 and 1890-91, during which was organised the revolution of its system of architectural education.

NO. 7, MR. EDWIN T. HALL, V.P.R.I.B.A.

MR. E. T. HALL, like Mr. STOKES, is serving as Vice-President of the Institute.

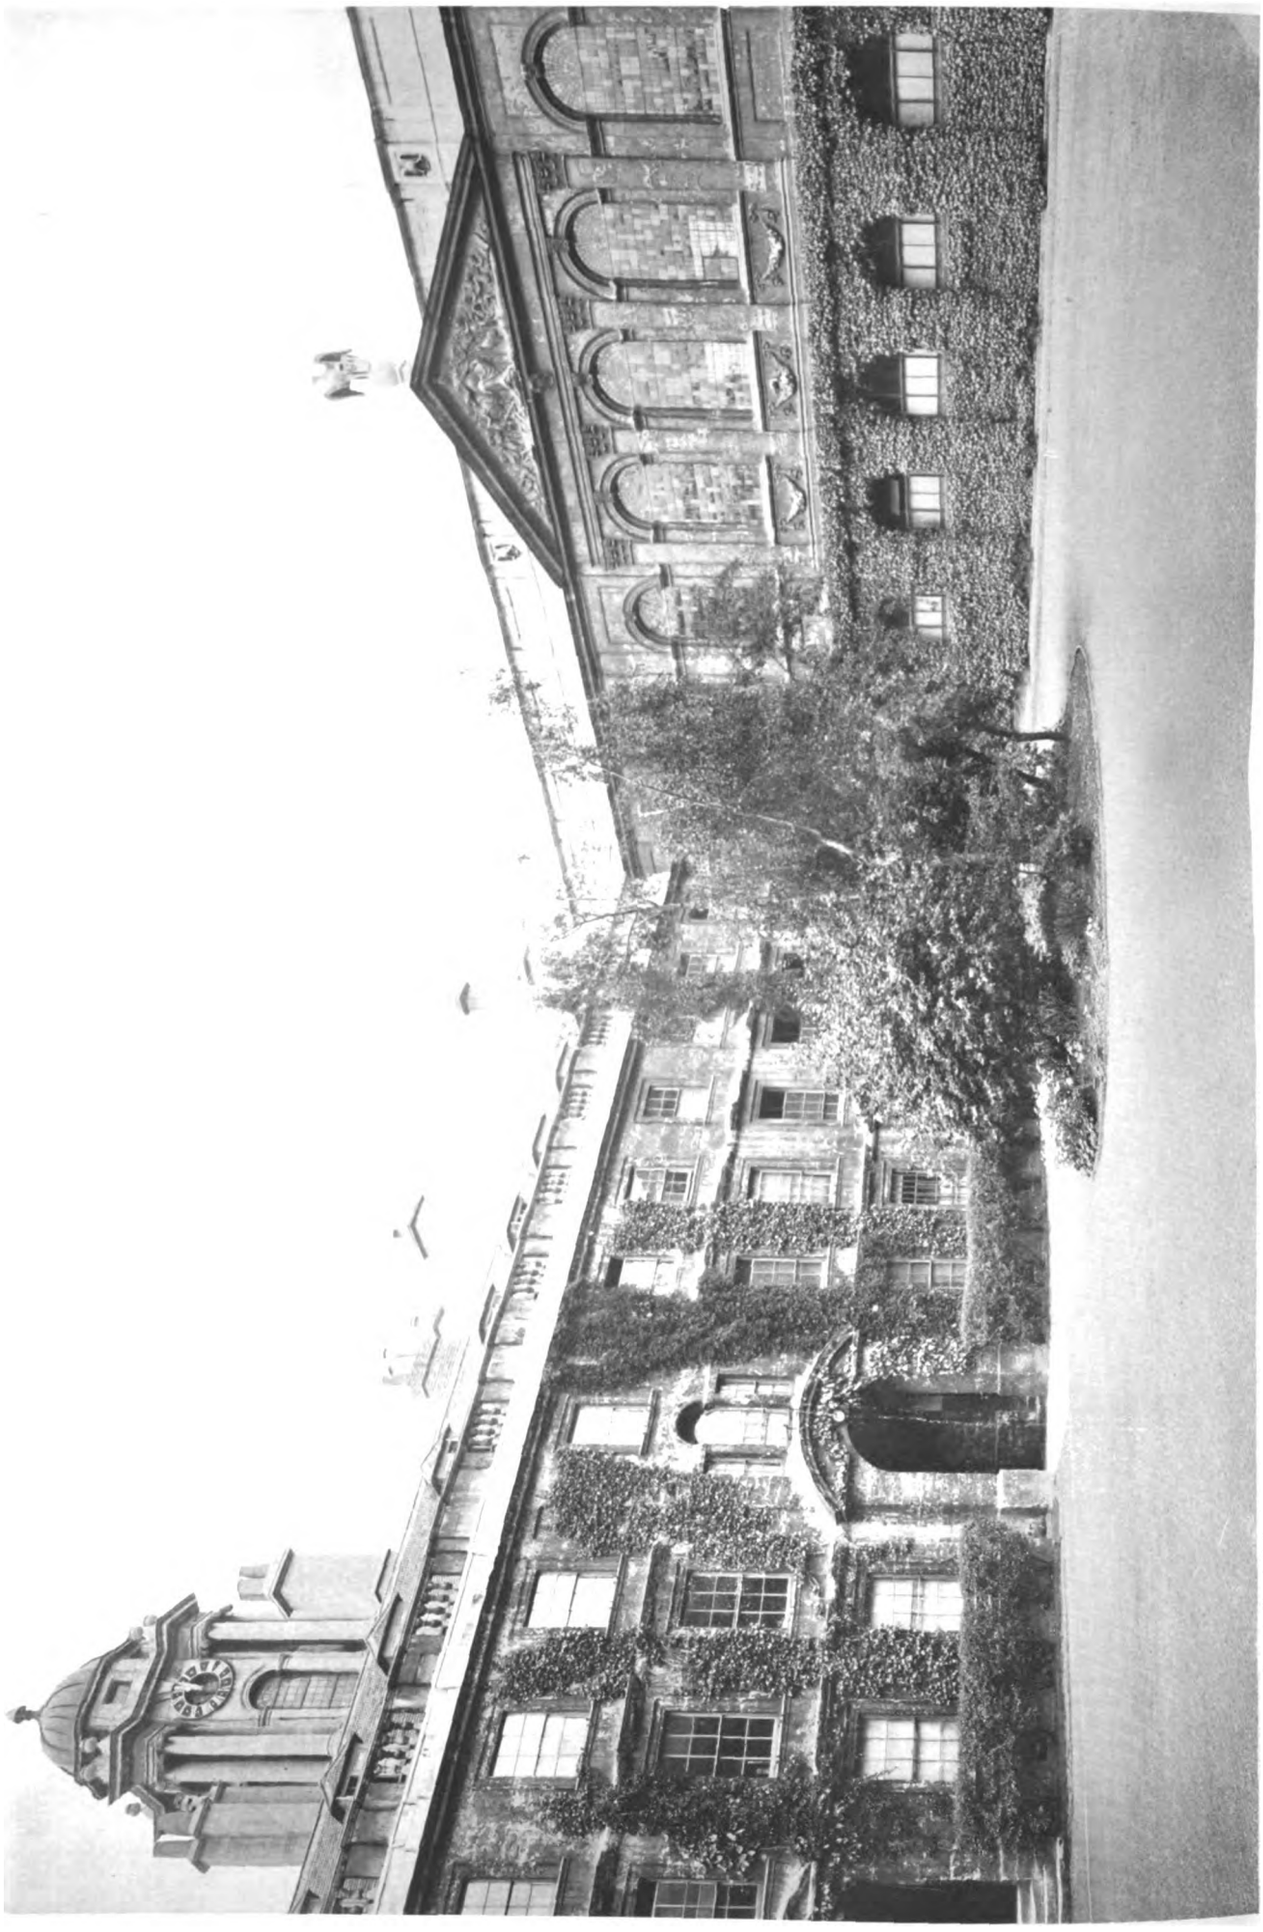
NEW CENTRAL FIRE STATION, MANCHESTER.

THIS group of buildings faces London Road, Fairfield Street, and Whitworth Street, Manchester. The total area is 5,463 square yards, and has been used to accommodate the fire department, bank, coroner's court, gas-meter testing department, police department, and a central courtyard for drill, &c. Williams Deacon's Bank, Ltd., have their premises facing London Road; the fire department occupies the Fairfield Street front, and has accommodation for seven engines and horses. Over the engine-house are the men's quarters, the electrical operator's room, the chief officer's quarters, and the hose tower. This tower is a prominent feature, and is used for the quick and economical drying of the hose after its use at a fire. In the buildings brick has been used, with terra-cotta facings throughout. The site cost about 25,000*l.*; the contract for the foundations was 7,720*l.*, and that for the superstructure was 75,000*l.* The architects are Messrs. WOODHOUSE, WILLOUGHBY & LANGHAM, of Manchester.

ISLINGTON BRANCH LIBRARY.

THIS branch library was completed in 1907 at a cost of about 6,600*l.*, of which 5,000*l.* was provided by Dr. ANDREW CARNEGIE. The accommodation provided comprises the following:—Basement: A lecture-hall 41 feet by 36 feet, which will accommodate about two hundred persons; also staff, store, and other rooms. Ground floor: Lending library 41 feet by 36 feet, designed to hold 20,000 volumes; children's library and reading-room, to accommodate 100 readers and store 3,000 volumes. First floor: Reading-room 41 feet by 36 feet, to hold about 120 readers and 150 periodicals. Librarian's room and other accommodation. The builders were Messrs. DEARING & SON, LTD., of Islington. The architect was Professor BERESFORD PITE.

NATIONAL TELEPHONE COMPANY'S PREMISES, GERRARD STREET, W.



THE illustration shows the new Exchange lately built in Gerrard Street by the National Telephone Company, and is commonly known as "Gerrard." The ground floor contains offices, and the switch-room, with top light, is on the third floor; the other floors being occupied by the staff and the complicated plant which goes to make up an "Exchange." The elevations to Gerrard Street and Lisle Street are in Portland stone and red brick. Mr. LEONARD STOKES was the architect, and Messrs. KILLBY & GAYFORD were the contractors.

A STONE DOORWAY IN THE RUE GHEERWYN, BRUGES.
From a Sketch by Banister Fletcher.

STRESSES AND STRAINS IN GIRDER WORK.*

(Concluded from last week.)

IN order to make this paper more practically useful to you I now propose to take you through the details of designing a steel-plate box girder of 50 feet clear span to carry a uniformly distributed load of 100 tons (diagram 5). The work should be systematically entered upon a sheet of foolscap, headed with the name of the job for which the girder is about to be designed, and then continued as follows:—

Steel Plate Box Girder.

Clear span . . . . . 50 feet
External dead load uniformly distributed . 100 tons
Mean depth of girder, say $\frac{1}{20}$th span . . 2·5 feet
Width of flanges (least width between webs 12 inches), say $\frac{1}{20}$th span . . . 2·5 feet
Approximate weight of girder—

$$\frac{WL}{400}\times\sqrt{\frac{L}{d}}=\frac{100\times50}{400}\times\sqrt{\frac{50}{30}}=12{\cdot}5\times1{\cdot}291$$

= 16·1375, say . . . 16 tons
Gross load 100+16 . . . . = 116 tons
Safe load per square foot on York stone bed 15 tons
Chamfer on edge . . . . . 3 inches
Length of each bearing surface—

$$\frac{\frac{1}{2}\text{ (100 tons load}+\text{16 tons girder)}}{\text{2·5 feet, width flange}\times\text{15 tons safe load}}=1{\cdot}55$$

say . . . . . 18 inches
Total length of girder 50+2(·25+1·5) = 53·5 feet
Effective span centre to centre of bearings 53·5−1·5 . . . . . = 52 feet
Stress in flanges at centre $\frac{WL}{8D}=\frac{116\times52}{8\times2{\cdot}5}$

=301·6, say . . . . . 300 tons
Factor of safety to limit deflection—

$$\frac{\text{span}}{\text{depth}}\times0{\cdot}3 \quad . \quad . \quad . \quad . = 6{\cdot}$$

Ultimate stress per square inch . . . 30 tons
Working stress per square inch $\frac{30}{6}$ . . 5 tons
Sectional area of each flange $\frac{300}{5}$. = 60 square inches
Angle bars, say 4 inches by 4 inches by $\frac{5}{8}$ inch.
Approximate thickness of flanges at centre $\frac{\text{60 square inches}}{\text{30 inches wide}}$ = 2 inches.
Approximate depth of web between rivet holes, 2·5 feet − 2 inches for flanges − 4 inches for angles . . . = 2 feet
Maximum shear = reaction at support = $\frac{116}{2}$ . . . . . = 58 tons
Maximum shear stress per foot in depth and per foot run horizontal $\frac{58}{2}$ . . = 29 tons
Diameter of rivets, say . . . . . 1 inch
Total depth of web − 2 rivet holes = 30 inches mean depth girder − 2 inches for flange − (2×1) for rivets . = 26 inches
Thickness of web plates, allowing 3 tons per square inch safe shear stress—

$$\frac{\text{58 tons}}{\text{3 tons per square inch}\times\text{26 inches width}\times\text{2 webs}}$$

= ·371, say . . . . . $\frac{3}{8}$ inch
Sectional area of one rivet . . . . . ·8 square inch
Safe shear stress per square inch rivet area, single shear . . . . . 4·5 tons
Double shear, $4\frac{1}{2}$ by $1\frac{1}{2}$ . . . = 6·75 tons
Safe shear stress per rivet double shear 6·75 by ·8 . . . . . = 5·4 tons
Number of rivets per foot run, double shear $\frac{29}{5{\cdot}4}$ = 5·37, say . . . . . 6 rivets
Pitch of rivets, $\frac{\text{2 webs}\times\text{12 inches}}{\text{6 rivets}}$. = 4 inches
Bearing pressure of rivets per square inch not to exceed . . . . . 10 tons
Actual pressure in holes of webs per square inch—

$$\frac{\text{29 tons stress per foot}}{\text{6 rivets}\times\text{bearing area per rivet }(1\times\cdot375)}=12{\cdot}8\text{ tons}$$

As this exceeds the limit the pitch must be reduced at ends to $4\times\frac{10}{12{\cdot}8}=3\,125$, say . . . . . 3 inches
But the 4-inch pitch may be retained if desired for $\frac{10}{12{\cdot}8}\times\frac{50}{2}=19{\cdot}5$ feet each side of centre.
Equivalent plate thickness of one side of four angles $\frac{4\ (4\times\frac{5}{8})}{\text{30 inches flange}}$. = $\frac{1}{2}$ inch
Least thickness of top flange, rivets in compression not deducted, 2 − $\frac{1}{2}$. = $1\frac{3}{8}$ inch
Plates in top flange, say 3 − $\frac{5}{8}$-inch plates = $1\frac{7}{8}$ inch
Least thickness of bottom flange—
Net section required . . . = 60 square inches
Net section of four-angle sides less four 1-inch rivets = 4 (4 − 1)×$\frac{5}{8}$. = 7·5 square inches
Net section of plates 60 − 7·5 . = 52·5 square inches
Net width of plates 30 − 4 × 1-inch holes . . . . . = 26 inches
Least thickness of flange = $\frac{52{\cdot}5}{26}=2{\cdot}02$
say . . . . . 2 inches
Plates in bottom flange, say one $\frac{3}{4}$-inch and two $\frac{5}{8}$-inch plates . . = 2 inches

Steel plates may now be obtained in one piece at ordinary prices. Up to 20 cwt., 30 feet long, $2\frac{1}{2}$ feet wide, $1\frac{1}{2}$ inch thick, 60 feet super, and at extra cost up to 2 tons, 60 feet long and 120 feet super, but only one of these limits may be reached in the same plate.

In this case it will probably be well to put a joint in the inner flange plates and the web plates. The angles may be in on length.

* A paper read before the Association of Engineers-in-Charge on April 14, by Henry Adams, M.Inst.C.E., M.I.Mech.E., Vice-President.

Digitized by Google

STEEL BOX GIRDER—50 FEET SPAN—TO CARRY 100 TONS

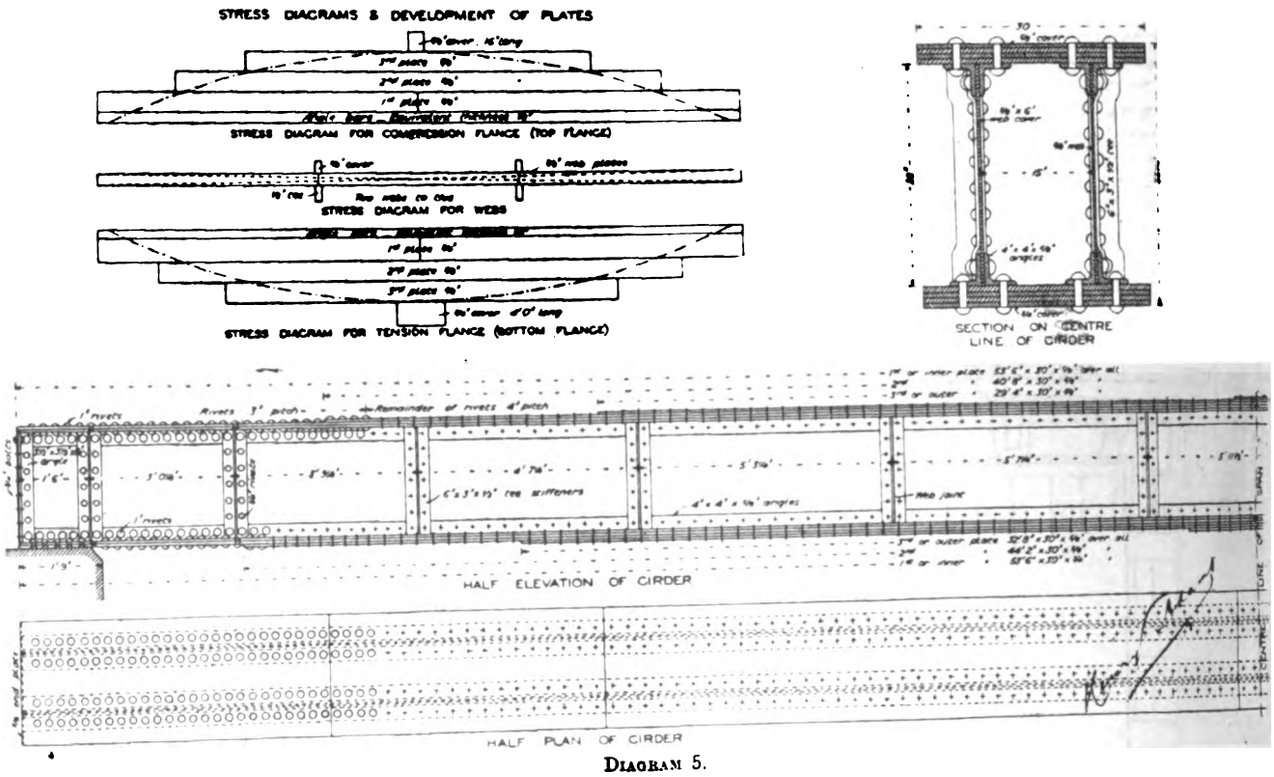

DIAGRAM 5.

Cover to joint in ¾ inch bottom flange plate.
Net sectional area of part cut through ·75 (30 − 4 × 1) . . . . = 19·5 square inches
Sectional area of one rivet, say . = ·8 square inch
Number of rivets each side of joint $\frac{19{\cdot}5}{{\cdot}8} = 24{\cdot}375$, say . . . . 24 rivets
Length of cover plate $\frac{24 \text{ rivets}}{4 \text{ in a row}} \times \frac{4\text{-inch pitch} \times 2 \text{ ends of cover}}{12 \text{ inches in 1 foot}}$ = 4 feet long

Cover to joint in ⅝-inch top flange plate being in compression with planed butt joints need only be small, say twelve rivets in two rows on each side . = 16 inches long

Cover to web plates on insides only, between angles behind stiffeners—
Thickness . . . . . ⅜ inch
Width . . . . . 6 inches
Rivets ¾ inch pitch, 4 inches

Stiffeners, between angles only, on outside:
At ends 3½ inches by 3½ inches by ½ inch angles. Over edge of bearing surfaces and 4 feet to 6 feet apart between, say 6 inches by 3 inches by ½ inch tees.

End plates to close girder, ⅜ inch thick, bolted through end stiffener angles by eight ¾-inch bolts and nuts.

Allowable deflection $50 \times \frac{1}{480} \times 12$. = 1¼ inches

Calculated deflection—
S = stress allowed, tons per square inch.
L = span in inches.
E = modulus of elasticity in tons.
D = mean depth in inches.
d = deflection in centre in inches.

$$d = \frac{SL^2}{4ED} = \frac{5\,(50 \times 12)^2}{4 \times 13{,}000 \times 30} \quad . = 1{\cdot}514 \text{ inches}$$

Permanent camber ⅛ inch to ¼ inch per 10 feet span, say . . . . . 1 inch
Building camber = 1·154 + 1 = 2·154, say 2¼ inch

The design may now be proceeded with, first finding the proper length of flange plates by drawing a parabola for each flange, of a span equal to the centre distance of bearings and a height equal to total thickness, including equivalent value of angles, to any convenient scales, the latter being to a larger scale than the former. This will be seen upon the upper part of the diagram. Where the parabola cuts the level of the inner edge of each plate, a distance equal to half cover, according to thickness, must be added to obtain the proper termination of the plate. Then the section, elevation and plan may be drawn in as shown to complete the design, and the actual weight may then be estimated.

It must not be supposed that in practice the designing is always as simple as this; often the work is only tentative, and has to be revised in different parts until a perfect result is obtained; but enough has been shown to indicate in a practical manner the subject of "Stresses and Strains in Girder Work."

In the discussion which followed the reading of the paper the CHAIRMAN (Mr. W. H. Maw), past president of the Institution of Mechanical Engineers, called attention to the scope that was left for the exercise of skill on the part of draughtsmen in considering the value of alternative methods of design after all preliminary calculations had been made, as, for example, thickening girder webs to reduce the bearing pressure in rivet holes as an alternative to reducing the pitch of the rivets, also the consideration of the depth of a girder where the cost of packing pieces behind the stiffeners would exceed the cost of joggling the ends and the general question of less depth and more weight, or *vice versâ*.

Capt. RIALL SANKEY, M.I.C.E., objected to the principle of stating an ultimate strength and then allowing a factor of safety. He preferred going direct to a working allowance for stress.

Professor ADAMS agreed with this in general, but in the particular example worked out in the paper the depth was reduced below the point of economy as regarded the girder itself for the sake of the economy preferred by architects in the height of their buildings, and the use of a sliding factor of safety compensated for the extra deflection that would have been produced by allowing the usual working stress. In reply to other criticisms the author stated the joint covers for angle bars were necessarily narrower by one thickness of angle flange, and the sectional area had therefore to be made up by giving an extra thickness to the cover. Upon structures of cast iron and mild steel stanchions a distinction was made between dead and live loads, but it was not usual or necessary in other cases unless in providing for quite exceptional circumstances. Uniform strength in a girder meant that the sectional area of each part was proportioned to the stress upon it, while uniform section such as was given by a rolled joist provided surplus material except at the one point of maximum stress. The practice of cutting the flanges away from the end of a rolled joist to enable it to fit between the flanges of another joist at right angles was reprehensible and might in some cases lead to failure. A

Digitized by Google

stanchion standing on a girder and bolted to it should have the holes properly rimered, and turned bolts driven in should alone be used; in fact, in all structural work bolts should be a good tight fit, and not the loose job that was commonly found. A rolled joist could not be considered to have the end built in to make it equivalent to a "fixed end" unless it went into a wall at least four times its depth.

The CHAIRMAN, in proposing a vote of thanks to Professor Adams for his paper, remarked that the lecture had not only been of high interest to those present, but that it also possessed a great permanent value and would, he was sure, be frequently referred to in the future. Professor Adams had dealt with his subject with great clearness, and they were much indebted to him.

ASPECTS OF APPLIED ÆSTHETICS.

AT the Royal Institution on Thursday of last week, Mr. James Paterson, A.R.S.A., R.W.S., R.S.W., delivered the first of a series of three lectures dealing with aspects of applied æsthetics. The lecture was entitled "How a True Art Instinct may be best Developed," and will be followed by (2) "Landscape Old and New" and (3) "Art and Ethics."

In his opening lecture, of which we give a condensed report, Mr. Paterson expressed his fear that in the multiplicity of interests which call loudly in these busy days for attention the still small voice of beauty is in danger of being drowned. But the arts hold a place in the development of nations and individuals, and exercise an influence wider and deeper than most of us realise. The civilisations of the past live mainly in what remains of their artistic product. Conditions are changing every day, but the spirit which demanded expression in the far-off days lives, and its relation to its own time—*i.e.* ours— is of the deepest moment.

Possibly, in recent years especially, there has been too much talking and writing about art; there cannot be too much thinking. We perceive at different periods, and not least in our own day, widespread diversion of aim among the producers, largely the result of a misunderstanding of what is really worthy. The attitude has too often degraded the divine instinct almost beyond recognition.

It has been rightly said, "Our whole chance of education lies in looking at things for what they have, not for what they have not." On all hands we find none so ignorant but that he can see faults, none so wise that they can discern beauty. Within reach we have noble architecture, great pictures, heavenly music, literature of the gods; and, alas! the travesty of all these. The intention to know and follow beauty presupposes the humble mind, willing to learn, reverently to inquire. Too much in the past, a nominal acquaintance with art (displayed in the acquirement of stock phrases of praise or blame) sufficed to make the so-called man of taste. No art can be treated as a pastime, and it is open to question whether the results of treating it as such have any but evil results.

What are the benefits we should expect from a more intelligent and widespread study of art? In all the depressing influences of daily life we have in it a palliative, an escape from the too insistent ego. Here we may find a perennial resource, growing and widening with the years, revealing ever new horizons. The ugliness of sin has often been descanted upon, the sin of ugliness has been too little realised. The entire neglect of art influences indicates a limited and stunted life; through their reverent approach a new interest is awakened in the sights, sounds and thoughts which throng our days, a new sense is developed of discriminating appreciation in our enjoyments, character is built up, sympathies in all noble things aroused which had otherwise lain dormant. By the formation of an educated public opinion all vulgarity is discouraged; the sins against good taste which make hideous beautiful country and hateful the aspect of our towns and villages, will become less possible.

Personal idiosyncrasy must decide the direction in which to develop our faculties. It is far better to become thoroughly familiar with even a limited region of artistic production than to embark on a hopeless attempt to compass its full range. A knowledge of one art does not qualify for definite opinions of praise or blame where others are concerned.

The battle which raged so long regarding the advisability of all children learning to draw has been won, and an enormous improvement has been effected in recent years which should have far-reaching effects. The training of the eye to see truly is, we might say, the beginning and end of all instruction in drawing; until truth is grasped and the hand trained to express it, beauty may be left to take care of itself. The training of the eye is not necessarily, nor is it primarily, concerned with art production. It is, strictly speaking, scientific in its methods and aims. The multiplicity of subjects in higher-class schools prohibit proper attention being devoted to the drawing lesson. But school days over, those who have the leisure, and most especially girls, should be encouraged to continue, or perhaps begin their education. It is astonishing what can be done by practice; and a pupil gifted with unusual facility is often excelled by one of seemingly far inferior talent. Attainment after all is not the real measure of success. Even to those without any special gift the gain accruing from a serious effort to master the difficulties of drawing is real and lasting. The stumbling-block to the average amateur is the impatience to proceed to the charm of colour. To produce a work of art in colour is impossible without a long and assiduous apprenticeship.

Much has been done and said in recent years to counteract the tendency to regard painting as the only form of art which amateurs should pursue. Modest crafts concerning themselves with making beautiful objects primarily produced for use are becoming less neglected and despised. "It is of the highest importance, nay, it is just the one thing of all importance, to show people what good work really means, and not so much to teach them to produce a good work themselves as to know it when they see it done by others," said Mr. Ruskin. The surest discipline through which to attain that sound judgment is the practice of drawing, leading to the exercise of one or other of the handicrafts. The great majority of people, distrusting their judgment in these matters, entrust the choice of everything in which their personality is most deeply concerned to the architect or house painter, with the result that in so many houses the environment in no way reflects the character and preferences of the inmates.

Among the truest devotees of beauty are many absolutely incapable of producing anything worthy of the name. The task is hopeless of prescribing rules to guide everyone who desires to raise his standard of taste. To the open and receptive mind progress may be slow, but should be sure; at every step the caution to ask, "Am I right to enjoy this or that?" following upon the pleasure received, not preceding it, being most necessary. The field indeed is wide; architecture, sculpture, and painting with their subsidiary and co-related arts of decoration invite us. Within the last 2,000 years or more how memorable have been the achievements. Greek and Roman sculpture and architecture, the mysterious period of Gothic creation in stone and wood and metal. Spain, France, Germany, the Low Countries, each has its memorable contribution to the wealth of the ages, holding pleasure and satisfaction for whoever has eyes to see. Our own little island has a worthy place in the records of the past, and affords a wide field to the sentient student.

Regional study of the order of the day, and in art also the surest foundation for wider and deeper appreciation lies in the caring for what of beauty we ourselves and our forefathers have accomplished. The material lies around us, and we cannot entirely ignore it. Without cultivated taste our so-called judgments are quite certain to be mistaken.

A dawning interest in artistic productions most commonly finds its first pasture in the work of contemporaries. The number of practising artists of all kinds is to-day so numerous, the circle is very restricted which does not include one or more within its orbit. Personal bias will thus account for much supposed æsthetic sympathy or antipathy; to many this is the beginning and end of their dealings with the subject. It frequently happens that the accident of personal acquaintance with an individual artist gives a bias from which it may take years to escape. Discrimination at this point of development is not to be looked for, although it may soon come into play if only through comparison between the various works of the favoured one, and his attention is drawn to the work of other men in the same direction. Probably he may have backed his appreciation by acquiring what was admired. The test of living with and daily scanning the acquisition probably reveals new beauties, but not improbably imperfections as well. Time alone will decide if a growing taste will allow the work to retain its position in his affections.

There are households, of course, where such considerations would be thought fantastic. Surroundings are regarded solely from the point of view of comfort, the pictures on the walls are part of the furniture, and neither worth a moment's thought. Such people may live in a clean pig-stye, but it is a pig-stye all the same.

Most people in caring for art of any kind naturally appre-

Digitized by Google

ciate in the first place that of their own time and of their own country. This appreciation is seldom, if ever, discriminating. The Royal Academy is annually thronged by crowds which never cross the doors of the National Gallery, and it is not doubtful that popular admiration seldom is attracted by the best picture. This interest, uncultivated though it be, is to be welcomed; what we seek is its development and deepening.

Free play may be given to personal bias, variety in conception, subject and execution has its appeal for different natures; but accompanying the pleasure derived from any work of art, or rather following closely upon it, the spirit demands an answer to the question, Am I right in my enjoyment? What is it that attracts me? Am I swayed in my judgments by motives alien to the work itself? It were well, perhaps, to hesitate before giving a positive opinion of unqualified disapproval of what at first does not appeal; but, on the other hand, unthinking acquiescence in popular or even expert applause is equally to be deprecated.

No standard can be given by which the uneducated may judge of works of art. Truth to nature is claimed by many as the ultimate and only test; but this is begging the question. Until our eyes are trained, we cannot be said to see even nature truly; when they are trained we see it differently. To judge a picture by our notions of what truth is may appear plausible; but what of decoration, of architecture? And yet we find many who should know better applying this standard. A curious and illuminating example occurs in the life of Sir John Millais. The minister of Kinnoul, in connection with a window which Millais had presented to the parish church in memory of his son, wrote to the artist as follows:—"On the design and blendings of colour I need not dwell, for they at once strike every beholder of average taste; but that which appears to me one of the greatest triumphs of the work is the marvellous perspective of the various landscapes. Painted glass in general, so far as my acquaintance with it goes, offers to the eye no more perspective than that which is seen upon a china vase in a teacup. The Kinnoul window is very different character, and is at once a window and a picture true to nature." The window was executed from the noble designs Millais drew from the Parables; but if the perspective is as marvellous as the good man thought, the window would therein have fallen short in the essential qualities of fine glass.

For the cultivation of judgment the study of the work of former generations is essential. The greatness of certain artists is beyond question, and not to feel this for oneself argues very limited æsthetic perception. To place ourselves in touch with the best of ancient art requires a cultivated imagination which is not commonly aroused, even in those who love beauty most, till youthful days are passing and past. Clausen says:—"The greatest service the old painters can do us is to steady our judgment, for we are peculiarly liable to be led away by following whatever fad happens to be in vogue at the moment."

But old painters cannot steady our judgment till we have acquired some sound idea of what is to be admired in their work. If a method were wanted it might be suggested that one artist be chosen for study whose works are accessible, say, in our National Gallery. Become familiar with them, returning again and again, not necessarily for a long time at once, but often. Compare his pictures with one another and also with those of his contemporaries. At a certain stage get someone like-minded, but further developed in culture, and compare judgments.

A common mistake is made in looking at too many pictures at a time. Had we only half an hour to spend in a gallery of masterpieces it were better to see and feel vividly the greatness of one picture than to be able to say we had seen all and yet have realised none. There is no final appeal in the ultimate questions of æsthetics, but we are far more liable to stumble in condemnation than when we confine ourselves to appreciation.

Supposing we have after much attention and study outgrown our early admiration of feeble and faulty things, it is not necessary to conclude that the art of our own day is unworthy of notice and approval. The cant of the old masters was never more prevalent than to-day. It is very certain that work is being produced at the present moment which will rank with the masterpieces of past generations when a few decades have passed. Living dogs become dead lions sometimes, and in the history of art those are remembered who bravely encouraged the struggle to achieve excellence by the artists of their day.

It would be futile to expect any absolute agreement on the part of those who have learned to care for what they feel to be supremely fine in any of the arts. In this department of human interest there is no common creed, no ultimate appeal. Therein lies much of its attractiveness. Enjoying to the full what we ourselves recognise as worthy, let us cultivate a broad catholicity and endeavour to sympathise with the seemingly limited, or even antagonistic, outlook of those who differ from us.

Art is a wide domain; the most gifted can only occupy a little corner of its territory.

THE INSTITUTION OF CIVIL ENGINEERS.

AT the ordinary meeting on Tuesday, April 20, Mr. J. C. Inglis, President, in the chair, a paper was read on "The *New York Times* Building," by Mr. C. T. Purdy, M.I.C.E. The following is an abstract of the paper:—

Early in 1902 the proprietors of the *New York Times* determined to move from the newspaper district near the City Hall to quarters in the newer part of the city. The site selected for the new building is bounded on the north and south by Forty-third and Forty-second Streets, and on the east and west by Broadway and Seventh Avenue. The Underground Railway, in curving from Forty-second Street into Broadway, crosses the north end of the property, passing through the basement of the building. This led to special features in the steel construction.

The length of the block is 137 feet 9 inches from north to south, the width at the south end is 58 feet 4 inches, while at the north end it is only 20 feet. On three sides, however, the basement storeys extend under the sidewalk. The height of the building from the sidewalk to the twenty-third storey is 329 feet, and above this is an observatory and lantern, the roof of which is 30 feet higher; the basement storeys extend 48 feet below the level of the sidewalk.

The framework of the building is constructed of steel, and the walls are of brick, with limestone and pressed-brick facings and terra-cotta trimmings. All the structural steel is covered and protected with terra-cotta material laid in cement mortar. Four high-speed elevators serve the building, and all heating is by means of steam.

The subway through which the Underground Railway runs is owned by the city, and in dealing with the subway problem two things were required:—First, the two structures of the subway and the *Times* building were to be entirely independent of one another; and, secondly, the building had to be protected from the vibratory effects of passing trains. In a number of cases the building columns came between the railway tracks, and the columns supporting the subway came through the lowest basement storey, which extends partly underneath the subway; but in practically all cases an air space was left round each column, and there was thus no connection between the two.

The building is supported on columns which rest on a rock foundation. The waterproofing of the basement extends continuously over the entire area and up the retaining walls to the street level. Mains are laid from the outside to a sump inside the building, so that no hydrostatic pressure can come on to the retaining walls.

Owing to the extreme narrowness of the building the stresses from wind load were considerable. To resist these the floor girders were increased in depth, and extra heavy girders were used in the spandrel construction round the building. In addition three special panels were used extending the entire width of the building, being formed by bracing between the columns. The total dead weight of the building is 33,611,000 lb. (15,000 tons). In no case was a column stressed to more than 13,000 lb. per square inch without wind load, nor to more than 19,500 lb. per square inch with it.

A serious question was the problem of vibration arising out of the Underground Railway. In addition to making the structure of the subway independent of the building, it was arranged to found the supporting columns of the former on cushions of sand, and thus still further to insulate the building. The results at first were quite satisfactory, and no vibration was felt from passing trains; but later distinct vibration was detected, and at last this became very pronounced. Seismograph observations were taken, and a thorough examination of the two structures was made.

The trouble disappeared when the railway company relaid the tracks through the building, all perceptible vibration then ceasing. The author considers, nevertheless, that the insulation of the two structures and the provision of the sand cushions for the subway columns have a material effect in producing this result. Under many conditions such insulation of structural members would be the most effective and

Digitized by Google

economical method of preventing vibration. It is stated that it was certainly efficient in the *Times* building, which has four railway tracks through it, and often three or four trains in the building at the same time, some stopping, and others passing through at high speeds.

EXHIBITION OF COTTAGE DESIGNS AT MANCHESTER.

AN exhibition of cottage designs promoted by the Council of the Manchester Royal Institution will be opened in the Manchester City Art Gallery in June. The promoters desire particularly to illustrate designs of workingmen's cottages which have already been erected, and of which reliable particulars as to cost and construction can be given, and they wish to discourage representation by picturesque drawings and to rely rather on working drawings and photographs to show the designs. They think that such an exhibition will be of practical value, and encourage the provision of better homes, and the desire to occupy and possess them, especially in this neighbourhood, which has hitherto been backward in this respect. The exhibition will be open for about nine weeks, and after about a month at the City Art Gallery the drawings will be moved firstly to the Queen's Park, and secondly to the Ancoats Museum galleries, with a view to interesting as large and varied a public as possible. A certain amount of space will be available for models.

It is also hoped to illustrate developments in town planning, and an effort will be made to take certain districts known to the local public, districts which are now being gradually built up without plan or regard to hygienic or artistic considerations, and to show how by a little thought they may be laid out on a proper planning scheme.

While the promoters have in view the desirability of exhibition designs for cottages which shall give definite information as to the sort of cottage which may be reasonably within the reach of the working man in town or country, and shall not be misleading from mere cleverness of draughtsmanship, they are prepared to receive suggestive designs for laying out groups of cottages, which may be of interest more from the point of view of collective design or of town planning than of individual dwellings.

Mr. Percy Worthington, M.A., F.R.I.B.A., is acting as hon. organising secretary to the exhibition, and will be glad to receive applications for forms and particulars from those interested in the subject, as landlords, architects, builders, or in any other way in the improvement of cottage building.

ESSENTIAL FORMULÆ IN STRUCTURAL ENGINEERING.*

By HORACE CUBITT, A.R.I.B.A.

FORMULÆ have been stated to constitute a mathematician's shorthand. From this it would seem evident that, where the facts which it is desired to represent are in no way complex or involved, the use of formulæ, or, in other words, the use of shorthand, is not necessary. Unfortunately, however, the large majority of engineering, and even architectural, text-books attempt to carry a cargo of formulæ which, instead of acting as useful ballast, is of such ponderosity as almost to sink the ship of the reader's interest and attention. My quarrel with the ordinary text-books is twofold: in the first place, because they quote formulæ for cases which can quite easily be worked out without such "aids"; and, secondly, because formulæ which are really necessary are often so disguised by inversions and transpositions of all kinds, and by the lack of standardisation in the symbols, that the average student, who in excess of zeal consults two or three text-books, usually gets his ideas of the subject hopelessly confused. A redundancy of formulæ is not, of course, confined to structural engineering. Many text-books dealing with the flow of water in channels quote, for instance, the formula $Q=AV$—i.e. the quantity equals the sectional area of the water flowing multiplied by the velocity of flow. It would be just as reasonable for a person keeping hens, and knowing the average number of eggs laid per week, to calculate the quantity of eggs produced in any particular number of weeks by such a formula as $Q=EW$.

In the present paper it will be my endeavour to demonstrate that, when a proper analysis of the question is made, the real essential formulæ for structural engineering purposes will be found able to be counted on the fingers of one hand.

Probably almost all that I have to say will appear obvious to those fairly well conversant with structural engineering. But some of the younger members may not be too familiar with my subject-matter, and possibly not a few municipal engineers, who have to deal with a multitude of matters of the most diverse character, will not object to having their attention invited to what is and is not essential in structural engineering formulæ.

The several members met with in structural work are able to be grouped under four heads:—

1. Where the forces act directly away from the member, producing tension.
2. Where the forces act directly to the member, producing in the first instance chiefly compression.
3. Where the forces act in a transverse direction to the axis of the member and induce a bending tendency, tension compression and shear being consequently produced.
4. Where members are subjected at the same time not only to direct tension or compression, but also to compression tension and shear due to bending.

Members in Tension.

In this case once the total stresses have been calculated—in framed structures usually with the aid of graphics—the determination of the required sectional area of the member to resist such stresses is most simple. No one thinks of using a formula. The ordinary rules of arithmetic, applied with common-sense, are in every way sufficient. There being no complex problem, the use of shorthand—or formulæ—is not necessary. But in several other almost as simple cases, to be subsequently referred to, formulæ for some unexplainable reason are often used.

Members in Compression.

Dealing with the most elementary form of construction coming under this heading—ordinary walls—calculations to determine thickness are rarely necessary. The thickness of walls is almost always fixed by schedule. But it is often necessary to calculate the size of piers carrying considerable weight. In this case no formula is used, the weight on the piers and the consequent load per unit of area are worked out by ordinary arithmetic, and, if necessary, the sectional areas of the piers increased, so that the allowable safe stress of the particular material per unit of area is not exceeded.

Coming to the question of reinforced concrete pillars we find that, in the report of the Reinforced Concrete Committee convened by the Royal Institute of British Architects, a formula is given which is applicable to columns whose lengths do not exceed eighteen times their least dimension, and in which the reinforcing bars are satisfactorily tied together in order to resist any bending tendency. Upon a little investigation, however, the process of calculation is seen to be so simple that to deal with it by means of symbolic representation appears merely an unnecessary burdening of one's memory with symbols. To obtain the safe bearing capacity of such a pillar it is simply necessary to find the sectional area of the whole pillar, add to this fourteen times the sectional area of the steel, and treat the combined area thus obtained as that of a plain concrete pillar in direct compression. To me it is more reasonable to think of this in plain English than to have recourse to symbols.

Those, however, not familiar with the subject may ask why the area of the steel is multiplied by such an apparently arbitrary figure as 14. The reason is that the respective moduli of elasticity of steel and concrete in compression are in the ratio to one another of 15 to 1. With the materials acting together the steel therefore provides a resistance per unit of area fifteen times that of concrete. If the steel is stressed so as to provide more than this resistance the concrete will suffer. It is therefore necessary to add to the area of the concrete fifteen times the area of the steel. But, taking the area of the whole reinforced pillar, this obviously includes both the area of the concrete and—putting it thus for the sake of clearness—one times the area of the steel; consequently it is necessary to add to the total area of the pillar fifteen minus one—viz. fourteen times the area of the steel.

When wood struts and iron and steel stanchions of a length customary in ordinary practice are considered the circumstances are different. In addition to the direct pressure there is the tendency to fail by bending, and to an average person it is practically impossible without formulæ to carry in the memory all factors which have effect in determining the strength of such members. Formulæ here appear

* A paper presented at the general meeting of the Institution of Municipal Engineers, held at the Building Exhibition, Olympia April 24.

Digitized by Google

to be essential, and of these it is generally considered that the most reliable is the adaptation by Professor Rankine of Gordon's formula.

Essential Formulæ (1) (as applicable to steel columns and stanchions):—

$$p = \frac{f}{1 + a\frac{l^2}{r^2}}$$

where p = unit breaking stress
f = unit elastic limit of material in compression (about 18 tons per square inch)
l = length
r = least radius of gyration
a = a factor usually taken as :—
$\frac{1}{18000}$ for free ends,
$\frac{1}{36000}$ for fixed ends.

} The same units of force, length and area being respectively taken throughout.

When this formula is used for calculating the strength of cast-iron columns or stanchions and wood struts, the constant a is usually taken respectively as eight and twelve times the value given above, and the value of f in the case of cast iron will be about 35 and in the case of deal struts about 2.2 tons per square inch.

Many authorities, however, consider that this formula should be applied, not with a fixed factor of safety, but that it should be used in connection with some other formula giving a greater factor of safety, in accordance with the increased liability of failure due to an increase in the ratio of length to least radius of gyration. Probably the most simple and appropriate factor of safety formula for steel stanchions is:—

$$\text{Factor of safety} = 4 + \frac{1}{100} \times \frac{l}{r},$$

l and r being in the same units,

which was given by Mr. E. Fiander Etchells in a paper read before the Civil and Mechanical Engineers' Society last year.

It is to be noted that in the application of the Gordon-Rankine formula there exists in the radius of gyration a factor whose determination from first principles will necessitate too great a demand upon the time and, I am afraid, also the mathematical knowledge of the average engineer. For all ordinary joists, angles and tees and compound stanchions of common type, the radii of gyration are given in the steel section books of the various manufacturers, but for wooden pillars, cast-iron columns and built-up stanchions of other than standard section it will be necessary to work out the radius of gyration, and for this there is a fairly simple practical method.

The radius of gyration is, as is well known, equal to the square root of the ratio which the moment of inertia bears to the cross-sectional area. This is usually written

$$r = \sqrt{\frac{I}{A}}.$$

The fact that it is the square root perhaps hardly needs emphasis, but the early edition of vol. iv. of the well-known "Rivington's Notes on Building Construction" contains an inaccuracy, the square root being omitted from the equation. The area can be simply obtained, and the least moment of inertia may be approximately deduced from that of a rectangular figure, which is $\frac{bd^3}{12}$, b and d equalling breadth and depth in the same units. As it is the least moment of inertia which is required to be obtained, it is, of course, the direction in which the post or stanchion is weakest which has to be considered, and the breadth of the section considered, except in the case of squares and circles, is greater than the depth. It is worthy of notice that the least radius of gyration of a rectangular section is $\frac{\text{least dimension}}{3{\cdot}47}$, and of a solid column $\frac{\text{diameter}}{4}$. In a hollow column it will be somewhat more than this, so to take $\frac{\text{diameter}}{4}$ in the case of all circular sections is to be at any rate on the safe side.

The use, however, of such elaborate formulæ as Rankine's for every single calculation to determine the strength of a member is in practice almost unknown. Either straight-line formulæ of the American type are adopted, or, as is more customary in this country, graphical diagrams, or tables, based on the more precise formulæ, are used, from which the safe unit stress in accordance with the ratio of length to least radius of gyration may be obtained. By the use of such diagrams or tables the calculation of struts or stanchions is a very simple and straightforward matter.

The following may be quoted as a type of the straight-line formulæ favoured in the United States as applied to steel stanchions:—$s = 12{,}000 - \left(50\frac{l}{r}\right)$, when s = safe unit load in pounds, l = length of member, r = least radius of gyration. with the same units of length and area.

The Bill which is being promoted by the London County Council in the present session of Parliament with a view to allowing steel-frame construction in London contains tables giving the proposed maximum safe loads on cast-iron, wrought-iron and steel pillars. Among the safe loads "with both ends fixed" are given the following (taken from the R.I.B.A. *Journal*):—

Ratio of length to least radius of gyration.	Allowable safe stresses in tons per square inch.		
	Cast iron.	Steel.	Wrought iron.
20	3·5	5·1	In all ratios of $\frac{l}{r}$ five-sevenths of the stresses specified for steel.
30	3·3	4·9	
40	3·0	4·7	
50	2·8	4·4	
60	2·4	4·2	
70	2·1	4·0	
80	—	3·7	
90	—	3·5	
100	—	3·2	
110	—	3·0	
120	—	2·7	
130	—	2·4	
140	—	2·2	

"Ends fixed" is perhaps rather a debatable expression, but the figures given in the table are very decidedly on the safe side, and may be applied to all cases where reasonable fixity is obtained. This table, it will be seen, does not go beyond an $\frac{l}{r}$ of 70 for cast-iron columns and 140 for steel columns or stanchions. This is contrary to general practice, in which members having ratios in the case of cast iron of 80 and in the case of steel of at least 160 or 180 are often used, and it is to be hoped that during the committee stage the Bill will be amended so as not to prevent construction based on these ratios being still permissible in London, not only in general building, but in work coming within the scope of the new Act.

The stresses on rectangular wooden pillars in special and temporary buildings or structures coming within the scope of the existing Building Act have generally been required not to exceed those given in the following table:—

Ratio of Length to Least Dimension.	Allowable Safe Stress in Pounds per Square Inch.	
	White and Yellow Pine.	Oak.
10	510	730
12	456	696
15	376	645
20	273	560
25	204	475
30	155	390

Members Subject to Bending.

It is with regard to members of this nature that modern text-books are responsible chiefly for confusion. In the early days of scientific research and the formation of engineering formulæ it was customary in every case to deal separately with the moment of resistance and the bending moment.

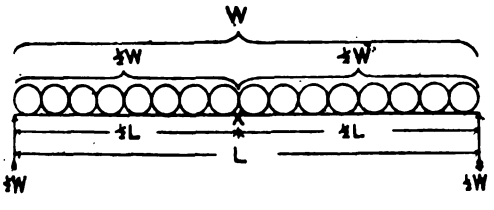
Essential Formula (2):—

$$M_r = M_b$$

when M_r = the moment of resistance
when M_b = the bending moment

} The same units of force, length and area being respectively taken throughout.

To make these as near as possible equal and thus provide efficiency with economy was the object of the engineer, and by the use of such simple and straightforward methods the solution of engineering problems was on a very clear and logical basis. Of late years it has become customary to



Digitized by Google

depart from this simplicity, and to quote formulæ applicable only to central distributed and other similar symmetric forms of loading, and with the symbols transposed in a manner to facilitate easy, and unfortunately blind, methods of working.

If, and this is the point I wish particularly to emphasise, nothing but central and evenly distributed loads were met with in practice there would be no great objection to this procedure. But loads unfortunately are so inconsiderate as not to adapt themselves to such formulæ, and very often are irregularly placed. I am afraid there are not a few of the younger generation who, while quite competent by means of the "stock" formulæ to work out problems where the loads are central or distributed, are unable to deal with a collection of "point" loads irregularly spaced on a girder. They have not devoted the necessary attention to the quite simple method of finding the bending moment of a supported beam—a method, of course, applicable to all kinds of loading.

I believe that this departure from the old established methods of finding the bending moment and designing the construction so that the moment of resistance is not of less value has been most unfortunate. Now that reinforced concrete work is becoming so general a proper understanding of the root principles of beam design, applicable not to a few but to all materials, is essential.

The method of finding the bending moment by obtaining the algebraic sum of all the forces on one side of the point in question is, of course, quite elementary and is explained in almost every text-book. It may be illustrated by quoting the method of arriving at the well-known bending moment $\frac{WL}{8}$ of a supported beam bearing a distributed load.

taking moments from, let us say, the left reaction about the point X.

$$M_b = (\tfrac{1}{2} W \times \tfrac{1}{2} L) - (\tfrac{1}{2} W \times \tfrac{1}{4} L)$$
$$= \frac{WL}{4} - \frac{WL}{8}$$
$$= \frac{WL}{8}$$

I feel bound to apologise for quoting such an elementary point, but it is of interest as illustrating the method of finding the bending moment of supported beams under any condition of loading, and further, it is these elementary points, in our days of higher education in the lofty and rather supercilious sense of the term, which we are liable to despise—and consequently forget.

To deal fully with the true mathematical method of finding the moment of resistance would take up considerable space, and to do this would be beyond the scope of what is intended to be a purely practical paper.

The practical method of obtaining the moment of resistance is by multiplying the section modulus (at one time often itself wrongly termed the moment of resistance) by the safe unit stress of the material. The section moduli of joists, angles, tees and compound girders of ordinary type are given in all steel section books, and are obtained in each case by dividing the moment of inertia by half the depth of the joist or girder. In rectilinear beams such as one meets with in timber work, the section modulus is $\frac{bd^3}{12} \div \frac{d}{2} = \frac{bd^2}{6}$, and in a steel joist or girder an approximation of the section modulus may be obtained by multiplying the sectional area of one flange by the depth of the joist. It is on this flange area stress that a very well-known formula is based—a formula not quoted for the reason that to my mind it is better forgotten, and reliance placed only in the simple formula $M_r = M_b$.

Some illustration of the applicability of the formula to a particular instance may not be undesirable. Taking the case of a supported beam bearing a distributed load:—

$$M_r = M_b$$
$$fz = \frac{WL}{8}$$

when W = load, L = span, z = section modulus, f = safe unit stress. The same units of force, length, and area being respectively taken throughout.

The formulæ for beams given in the report of the R.I.B.A. Reinforced Concrete Committee need perhaps some little investigation before it is discovered that to a great extent they are old friends in new dresses. It is desirable first to look back and realise the exact principles upon which all beam formulæ are based.

In the modern type of steel joist composed of a single material offering equal resistance to compressive and tensile stresses, the neutral axis is situated at the half depth of the section, and the area of the compression flange has to be exactly equal to that of the tension flange. In the old, practically obsolete, type of cast-iron girder—a girder composed of material offering much greater resistance to compressive than to tensile stresses—the circumstances are different, and the area of the tension flange must be about six times greater than the minimum area of the compression flange in order that the material may be stressed according to its respective capabilities in tension and compression, and the neutral axis in this case does not coincide with the half depth, but, with the centre of gravity of the section.

Coming to reinforced concrete, we have here a combination of materials, of which not only is the safe stress of the steel, which takes up the tension, about twenty-seven times that of the concrete which takes up the compression, but also a further difference of characteristics has to be considered, as the modulus of elasticity of the steel is about fifteen times greater than that of the concrete. The steel, that is to say, is this much stiffer than the concrete. Thus, prior to the ultimate provision of the materials in the ratio demanded by their respective safe resistances—a process to some extent analogous to that adopted in the case of a cast-iron beam—it is necessary to find the neutral axis, for the position of this will greatly affect the moments of the resisting stresses in the steel and concrete.

(To be continued.)

OUR CONTEMPORARIES FROM OVER-SEAS.

THE *American Architect* contains illustrations of the dam and power-house at McCall Ferry, Pa., which, though primarily an engineering work, is really an admirable piece of real architecture. Not only is it here shown that utilitarian structures, for which the engineer is mainly responsible and of which he is usually the sole designer, can be made beautiful with the expenditure of mind rather than money, but we have also an admirable example of how a concrete building can be treated so that it retains its expression of monolithic construction whilst at the same time presenting high architectural character. Ornament there is none; dignity, power, rhythm, composition are dominant, and a very fine presentment of architecture is the result. The architects, to whom credit for this remarkable work is due, are Messrs. Trowbridge & Ackerman, of New York. By way of contrast, we suppose, the University Club of Chicago is illustrated. Of this we will say nothing, except that we do not consider a literal transcription of fifteenth-century English detail, with an occasional soupçon of French thirteenth-century work, to be the most suitable dressing for a twentieth-century twelve-storey building in Chicago.

The Architectural Review (Boston, U.S.A.) has an attractive and fully illustrated article on "Half-timber Buildings of Saxony," with examples from Stolberg, Wernigerode, Halberstadt, Quedlinburg, Marburg, Osterwieck, Neuhaldensleben, Gardelegen, Flechtingen, Homburg, Schleusingen, Halle and other places. The type of work here described is not, however, confined to Saxony; the city of Brunswick and its neighbouring towns are full of it. A good example of a high-class flat building of eleven storeys, by Mr. Charles A. Platt, is illustrated, together with some of the interiors—quite good.

The Engineering Digest (New York) has an advance notice of a forthcoming book on the history of the slide rule, an instrument of which in this country the use is now almost a forgotten art, but was much appreciated in the eighteenth century. In America its employment seems to be gaining favour with the introduction of new and improved types.

Digitized by Google

The Engineering Record (New York) contains a trenchant criticism on the defects of architects' specifications for reinforced concrete structures, from an address delivered at the Armour Institute of Technology, Chicago, by Mr. Ernest McCullough, which is worthy of study on this side of the Atlantic as well as in the United States.

La Construction Moderne for this week should be interesting to our younger readers, as it contains illustrations of a French rendering of a very similar subject to that of the last Soane medallion competition. The designs are given that have won the first and second prizes in the Concours Achille Leclère, the subject being "Un grand Casino de bains de mer," and the successful authors M. G. Bellou and M. G. Migeon.

NOTABILIA.

THE first part of *Engineering Wonders of the World* has an article on "Ancient Engineering" containing some good illustrations of prehistoric stone monuments and Roman bridges and aqueducts.

The Building Exhibition.

SIR,—I am very pleased to read Mr. Keen's letter in the current issue anent the Building Exhibition, and I deplore the lack of enterprise evidenced by the direction in omitting the customary display of "architecture on paper." The collection of poster designs by no means compensates for the omission. Surely Mr. Montgomery dd not fear that the public interest was not expansive enough to enjoy the two displays? Indeed, if there be any truth in the notion that the appetite grows by what it feeds upon, Mr. Montgomery should have felt encouraged by the extreme interest displayed in former years in the architectural drawings; and in repeating the exhibition of the latter he would have been insuring an interest in the posters. The Architectural Room at the Royal Academy is no criterion in this respect, for it merely acts as the conservatory or staircase for the heated reception-rooms. The neglect of architecture has been of too long standing on the part of the public authorities; and Mr. Montgomery may, if he chooses, be a pioneer in regard to a better condition of affairs by reviving the exhibition of drawings two years hence and by allotting it a much better position than hitherto.—Faithfully yours,

PERCY L. MARKS.

Albert Buildings, 49 Queen Victoria Street, E.C.

SIR,—Like Mr. Arthur Keen, I am one of those—and they are many, to judge from the sentiments my friends express—who regret that the Exhibition this year does not include a successor to the excellent collections of architectural drawings and photographs that you, Sir, have organised on former occasions. Not only is it the fact that many drawings, highly interesting to architects and other visitors to the Exhibition, are unsuitable for the Royal Academy, but the space that body allots to architecture is, as is well known, quite insufficient for all that are sent in, and many are excluded not because they are inferior to those hung, but because there is not room for them, and they have been unfortunate enough to be the wrong shape or size to fit in with the mosaic that the Academy hangers present to us year by year.

It is not only the architects who like to show their drawings that miss this part of the Exhibition, but also the non-professional visitors. If I remember rightly, H.R.H. the Princess of Wales took a great interest in the drawings and photographs shown at the last Exhibition, and I am quite sure that her Royal Highness was only one of many visitors with the same appreciation. In fact, it is because we believe that others besides our professional brethren look at the drawings that we architects are willing to have our work exhibited.—Yours truly,

A FORMER EXHIBITOR.

The Chemistry and Physics of Building Materials.

SIR,—In reference to your review of my book and the useful criticisms therein contained, may I point out that, although it is not to be expected that everyone will be satisfied with the relative amount of space devoted to different topics in a small volume covering so much ground, the test for white lead, of absence of which your reviewer complains, is given and given under this particular material. On page 318, in reference to impurities likely to be present, the following paragraph occurs:—"Any sulphur compound will, when strongly heated with sodium carbonate on charcoal in the reducing flame, produce sodium sulphide, and if the freed mass be placed on silver (a coin) and wetted, a brown stain on the metal will result from the presence of this sulphide." The book is not a laboratory manual, but the use of the blowpipe will be found described in an earlier chapter.—Yours,

ALAN E. MUNBY.

We have submitted Mr. Munby's letter to our reviewer, and the following is his reply.—ED.

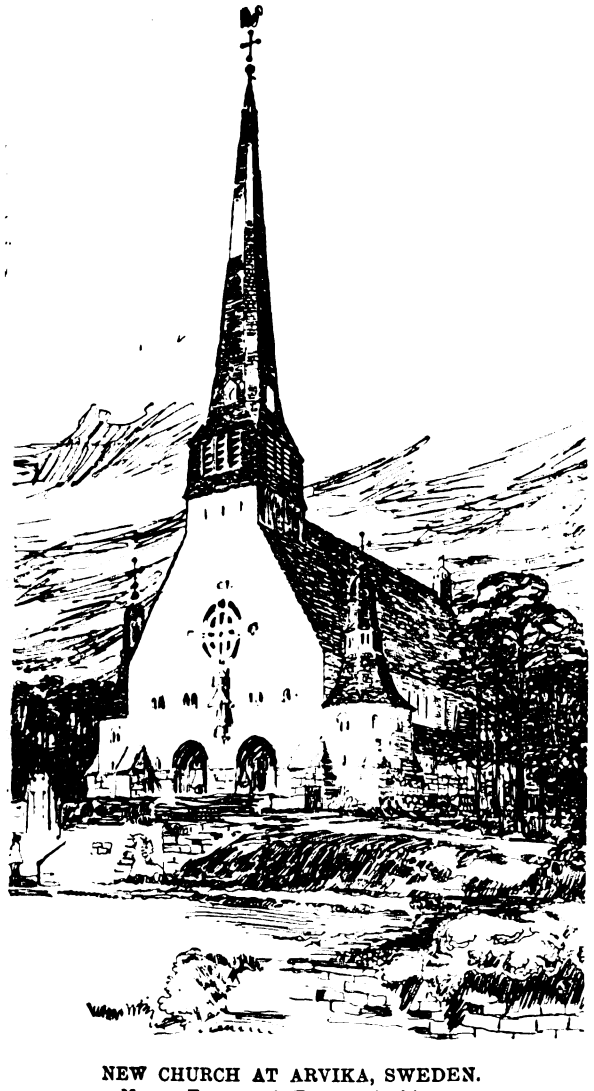
I admit that I have not expressed myself quite clearly. The substitution of one little word, "as" instead of "for" determining, &c., would, I think, have made my meaning more obvious. My point is that Mr. Munby gives the test to which I referred as a test for sulphur compounds, but does not impress upon the architectural student who is a tyro in chemistry the connection between the sulphur compounds and the trade qualities of white lead with which he has become acquainted. Mr. Munby credits the young architectural student with greater powers of deduction than he usually seems to possess when he steps outside the field of æsthetic studies to those of a scientific character.

THE REVIEWER.

GENERAL.

The First Commissioner of Works has appointed Mr. Arthur I. Durrant, M.V.O., Deputy Controller of Supplies, to be a Principal Clerk in H.M. Office of Works, to deal with questions of contracts.

Mr. J. Parkinson, architect and surveyor, Lancaster, who died on April 3, left estate value 9,988*l.* 5*s.* 6*d.* The bequests include 50*l.* to the Architects' Benevolent Society.



The Duke of Argyll will perform the opening ceremony of the Imperial International Exhibition, to be held this year at the "White City" at Shepherd's Bush. The exhibition grounds, which last year extended over 140 acres, have now been increased to 150 acres, and a number of buildings have been added in which many interesting exhibits will be housed.

At a Meeting of the members of the Institution of Municipal Engineers resident in the Home Counties District (Northern Division), which includes Bedford, Buckingham, Essex, Herts and Middlesex, held at Olympia on the 24th inst., Mr. Henry C. Adams, A.M.I.C.E., A.M.I.M.E., A.M.I.E.E., consulting engineer, of 60 Queen Victoria Street, E.C., was elected chairman of the district committee and a member of Council of the Institution. Mr. Bernard Partridge, Surveyor's Office, Walthamstow, U.D.C., was elected honorary secretary, and an executive sub-committee was appointed.

The Surrey Education Committee have now adopted the scheme for the provision of a technical institute and boys' secondary school at Woking, close to the station, at an estimated cost of 22,000*l.*

At the Last Meeting of the Glasgow Corporation a member said he would be glad if the Convener would give some more information as to the position of local manufacturers in regard to quick-drying paints, which were made at other places in this country and abroad, and were sold in competition with the local article. It was believed that some of these products did not comply with the requirements of the Petroleum Act, and consequently their use, carriage by rail, storage, &c., without being properly labelled, was fraught with danger. He understood that paints with a lower and more dangerous flashpoint could be made much more cheaply. It was so far good that the chief inspector should visit those who manufacture in this city, but something more seemed necessary to ensure, as suggested in the minute, that "all persons dealing with the material in question should be uniformly treated." It was obviously unfair that local men who complied with the Act should be placed at a disadvantage. The Chairman (Bailie Shaw Maxwell) said he was assured everything was contained in the minute. They would, however, keep in view the point raised.

NEW CHURCH AT ARVIKA, SWEDEN.
Messrs. TENGBOM & TORULF, Architects.
(From *Byggnadstidnungen.*)

THE WEEK.

THE annual general meeting of the Royal Institute was, as usual, somewhat of a farce, with Mr. WOODWARD as the chief player. Each year this gentleman sensibly and logically criticises the report of the Council, but nobody seems one penny the worse, and the Council still go on managing the affairs of the Institute in its own way and keeping the members as much in the dark as possible as to what it is really doing. The annual report of the Council should be a full account of their stewardship by the outgoing members who are seeking re-election; instead it is the minimum of information that may be expected to keep the electors quiet and ready to cast their votes in favour of the present members of the Council. Mr. EDWIN T. HALL once more assumed the rôle of the heavy father, in which he has become so proficient, and assured the few members present that if they only knew how much the Council really did do, and the vast amount of time and ability it gave to safeguarding and promoting the interests of the members, they would be good boys, shut their eyes and open their mouths for the inestimable privileges that the Council will procure for them—some day. This is the backbone of the present Council's policy; the ordinary members of the Institute must have blind confidence in the wisdom and energy of the members of the Council and must not want to know all about what the Council is doing, or whether it is doing anything. The diplomacy of the Council far surpasses that of MACHIAVELLI or RICHELIEU; it is stealthily doing all sorts of wonderful things, which must not even be whispered lest some of the myriad cords of the Council's statecraft be snapped and all the skilful schemes gang agley.

WHEN the question of registration is broached and the Council is asked what it is going to do now that it knows that of all the architects in the kingdom who care to express an opinion a majority of eight to one is in favour of registration, its answer, per Mr. HALL, is wait—elect us for another year, and then you will see—what you will see. Under our wonderful scheme of Licentiates all the architects of the kingdom are going to join the Institute, and then we will do something. Only re-elect us for another year. We are not a bit tired of being on the Council, as Mr. WOODWARD has suggested, even though the time we spend on committees and council meetings—and dinners—does diminish our incomes by 1,500*l.* to 2,000*l.* a year each. Or at least it would do if we were paid for our time on the usual professional scale. You have not seen the new Charter, which we have kept quite safe for three months, and very shortly—after you have voted and, we hope, re-elected us for another year—you shall have laid before you some wonderful new by-laws which have received most careful consideration.

POSSIBLY, if the present members of the Council are not all re-elected, the new by-laws may receive a little revision before they come before the general body of members; they have certainly been long enough in preparation for the present members of the Council to forget some of the many things that they have promised should be dealt with by "the new by-laws." As determining the future course of the Institute, the by-laws are in a sense more important than the Charter itself, and they may easily be drafted with a bias against the principle of registration. Mr. HALL says the basis of the new Charter was agreed unanimously; therefore he wants the members to once more be good boys and accept the by-laws as the Council drafts and presents them—but the present members of the Council must be re-elected first.

IT is really very modest of the Council not to explain fully to the general body of members all the great and wonderful things it does and the fatherly care and advice it bestows on the little boys in the lower forms. For example, no mention was made in the report of the advice given to members of the Institute respecting the competition for Concert Hall, Eastleigh. This advice appeared in the Institute Journal of April 3 last. The date for sending in drawings was March 24.

THE Ulster Society of Architects has taken the opportunity of the loan of the prize-winning drawings of the Royal Institute's student competitions for an annual exhibition at the Belfast Free Public Library, Royal Avenue, to celebrate the opening of which the president of the Society, Mr. W. J. GILLILAND, F.R.I.B.A., held a reception, and in his speech during the evening laid stress upon the importance of the authorities of the recently established Queen's University, Belfast, following the lead of Liverpool, Manchester and Sheffield, and providing the proper equipment and a teaching staff for architecture.

THE first public museum devoted exclusively to heraldry that has ever been founded in the British Isles has been opened by his Excellency the Lord Lieutenant of Ireland at the Office of Arms, Dublin Castle. It has been established mainly through the efforts of Captain WILKINSON, Ulster King-of-Arms. Heraldry as a science is one of considerable interest, and deeply fascinates its votaries, but it is also the repository of much excellent art, and as such a museum of heraldry is of widespread value. Although this museum is situated in Dublin, it is not confined to Irish objects alone, but embraces the whole field of European heraldry. This is a wise policy, for with so good a start as has been made, there is no reason why the Dublin Museum should not be the headquarters of heraldic students, a body that is increasing in numbers year by year.

ARCHITECTURE AT THE ROYAL ACADEMY.—I.

THE most striking feature this year of the Architectural Room at the Royal Academy is the awful disregard of anything like propriety in the hanging of the drawings. It would seem that the Academician in charge had first of all settled the principle that buildings for similar purposes should be grouped together—ecclesiastical, municipal, educational and domestic—a principle with which we cordially agree. Then that he had selected the drawings for "the line" and directed their position. So far, so good; and we have no fault to find with the selection and placing. But after this the débâcle—the hangers have worked their own sweet and unreasoning will, with the kindly intention of giving as many poor architects as possible the privilege of occupying a corner in the inadequate space that is all the Royal Academy grants in its annual show to the Mistress Art.

And away the hangers went at their job with a hustle. Bird's-eye views! Sky them, so that the birds may not have their range of vision unduly taxed. Drawings with a low horizon! Put them on a level with one's knee. Small and delicate drawings! Stick them on the skirting, or as near the cornice as possible, or tuck them into an odd space between big half-inch scale, powerfully rendered drawings. This sort of thing has been seen in previous Academy exhibitions, but we think that on the present occasion the hangers have surpassed all their previous efforts in this direction. No better proof of the necessity for an independent display of architectural drawings, at the Building Exhibition or elsewhere, could be given than this year's Architectural Room at the Academy. No wonder the general public only go there for a quiet rest when they have done, or are done up by, the oil-paintings, and lack capacity for any more cups of tea.

The place of honour on the west wall, devoted to ecclesiastical work, is occupied by Mr. Temple Moore's "New Nave, Hexham Abbey, Northumberland," the exterior and interior of which are represented in excellent pencil drawings showing a scholarly design, of which the best commendation is that it looks like old work in feeling and spirit but is original in essence, such a design as Mr. Moore might have produced had he lived when the Abbey Church was built, but still imbued with his own personality. Next to this hangs Mr. Arnold Mitchell's design for "Chapel at Berndorf, Austria," for Herr Arthur Krupp. This is of a distinctly Sussex type in composition, low and with a central tower, modest and squat in form; but the detail, though English Perpendicular in motif, is distinctly twentieth century. The interior shows a somewhat original treatment, low pointed arches dividing the nave into bays with low-pitched polygonal panelled ceilings, and under the tower a circular domed ceiling with a distinctly Renaissance touch. The interior of another design for "Proposed Chapel, Berndorf, Lower Austria," by Mr. John T. Lee, is a very fine design, dignified and stately, and free from all affectation or undue straining after originality, which quality is, however, attained without obvious effort.

Mr. Temple Moore is also represented by his "New Choir and Transept, Ecclesall Church, Sheffield," a pleasant interior, in which quaintness is obtained by the use of irregular spacing and forms of arches. Professor Beresford Pite's "English Mission Church, Safed, Galilee," is naturally a small building, in which an attempt has been made to impart local feeling by the use of detail of the character that one might suppose to have been employed in Herod's Temple. Mr. W. Campbell Jones's "School Chapel, Tonbridge," is shown by two drawings, respectively of the exterior and interior, the former beautifully showing a quite scholastic type of Perpendicular with good modern feeling, and the latter, simple in general treatment, emphasising the richly designed reredos.

Messrs. Douglas & Minshull have only one drawing in the exhibition, "New Chancel, Vestries, &c., Church of St. Andrew, West Kirby," a modernly treated version of Perpendicular shown in a good perspective, with an original and piquant central tower, or rather enlarged flèche, over the crossing, apparently of timber covered with slate, set diagonally to the axial lines of chancel and transepts, and suggested by French work. Mr. Louis Ambler's "Completion of St. Michael's Church, Sutton-in-Ashfield, Notts," is of a more conventional type of Early English work, with broach spire to the tower. A very quaint drawing shows Mr. J. Harold Gibbons's "Mortuary Chapel and Cloisters, St. Cuthbert's Church, Kensington," which looks to have some good work, but being a drawing that *ought* to be near the eye, is, of course, hung at a height at which it can hardly be seen.

A striking design is Mr. Walter Tapper's "Chapel for the Community of the Resurrection, Mirfield," simple, bold, and original, without affectation. To the inquirer as to what "style" it is in, we should say that it possesses style but follows no style. In that it makes use of semicircular arches it might be referred, at a distance, to Romanesque or to Renaissance. It possesses the dignity of the round-arched German work, and the interior suggests study of that period. The chancel screen, on the other hand, apparently of stone with metal grille, is reminiscent of Early French and Italian Renaissance. We can, therefore, only assure our inquirer that the "style" of this design is that of its author, an architect who has studied and assimilated the lessons of old work, and, instructed but not fettered thereby, has produced a modern and individual work of high-class architecture. Mr. Burke Downing's "New Church of St. Barnabas, Mitcham, Surrey," which hangs next, is of quite different character, and yet, in its turn, likewise good architecture—modest in height, no doubt for considerations of cost, yet picturesquely grouped and well detailed, based distinctively on English village church architecture of the fifteenth century, yet modern in treatment. Mr. Edward B. Muff's "A London Suburban Church" is one of the small and delicate drawings stuck on the skirting. The design is that of a single-span nave with processional aisles simply treated, and with a saddle-back tower.

Mr. Frank L. Pearson's "Cathedral School, Cloisters and Library, Truro," are shown in a big drawing whose chief attraction is the cathedral, which forms the background to the buildings that are the ostensible subject. Mr. William H. Coate's "Design for a Church in East Anglia" looks good, though the turret stair to the tower rather, to our mind, detracts from the East Anglian feeling, notwithstanding that such features may be found in that part of England. "All Saints Church, Bedford," by Sir A. W. Blomfield & Sons and Mr. G. P. Allen, is good, with Perpendicular traceried windows of a more correct and conventional type than is the fashion in modern work, and has at the north-west angle a tower with spire. The "Church of the Good Shepherd, Lee: Exterior," by Messrs. F. H. Greenaway & J. E. Newberry, is an example of a cheap suburban church with nave and aisles under one roof rescued from poverty by a good tower. Decorated for a change is the period on which the detail is founded. The Decorated period is also followed by the next drawing, showing in pencil and tinted elevations a quiet and refined design for the "Church of St. Andrew, Purlwell, Yorks," by Messrs. E. B. Hoare & M. Wheeler, which, however, we think is spoilt by the sudden change half-way up of the plan of the tower buttresses from rectangular to diagonal. Mr. William J. Devlin's "Design for Church of the Holy Cross, Crosshill, Glasgow: Interior," is a Classic conception, severe and dignified, with the nave divided into squares by piers with columns between, thus including two bays of the nave arcade in one compartment of the nave. "St. Wilfrid's Church, Bognor: Interior, looking East," by Mr. G. H. Fellowes Prynne, is apparently a study in the polychromatic use of materials, which in this case are red brick with plenty of stone, and green wood panelling to the lower part of piers and walls. The result is rather fidgety in the drawing, but everything would depend in execution on the exact tints of the brick and stone, and the lighting by

Digitized by Google

which they were seen. Mr. J. COATES CARTER'S "New Church, Pontypool," is an excellent design in a severe early type of treatment. The design for "St. Chad's Church, Far Headingley, Leeds: New Chancel and Vestries," by Messrs. JOHN GIBBONS & SON, is an excellent composition. On another drawing described "Designs for Church Fittings," by the same architects, is an elaborate, clever, and quite modern design for St. Chad's font and cover, and on the same sheet a pulpit and screen for All Saints Church, Stretford, equally clever. Mr. P. NAPIER HEMY'S "Design for a Church at Ascot" is apparently a first study, quite modernly treated with much originality, which seems to want further consideration and pulling together to render its parts harmonious.

(To be continued.)

THE HISTORY OF WESTMINSTER ABBEY.*

JOHN FLETE was a monk of Westminster from 1420 to 1465, and the only mediæval writer who attempted a history of the Abbey. He has been somewhat eclipsed by the excellent history compiled three centuries later by WIDMORE, who availed himself of FLETE'S labours and supplemented them by a diligent investigation of the treasures of the Muniment Room. Thus it is that FLETE'S work has never been printed until it has now been rescued from its obscurity by Dean ROBINSON.

JOHN FLETE'S intention, as expressed in his preface, was to write the history of his Abbey from the time of LUCIUS, first King of the Christian Britons, A.D. 184, down to the year A.D. 1443, the twenty-second year of the reign of HENRY VI. Modesty possibly led FLETE to fix this year for the completion of his history, for he then became Senior Warden of Queen ELEANOR'S manors, and subsequently occupied other positions of dignity. For some reason not related, but quite comprehensibly through his devotion to the important and responsible duties of his several offices culminating in that of Prior, his history goes no further than the death of NICHOLAS LITLYNGTON in 1386.

The early history of the church at Westminster is briefly given by FLETE, on the alleged authority of an ancient Anglo-Saxon chronicle, which, Dean ROBINSON points out, cannot be much earlier than the middle of the twelfth century. The building of a new church by SEBERT, King of the East Saxons, and its consecration by St. PETER, referred to in the putative Anglo-Saxon chronicle, is described at length and in fuller detail by transcriptions from four narratives—(1) "another ancient chronicle," found in the life of St. EDWARD, by AILRED OF RIEVAULX (A.D. 1163); (2) the life of St. MELLITUS, by GOSCELIN, a monk of St. Bertin; (3) the chronicle of SULCARD, a monk of Westminster in the time of Abbot VITALIS (1072-81); (4) a chronicle called "Liber Regius," which Dean ROBINSON has not been able to identify.

The historian then goes on to quote various Papal bulls and royal and episcopal charters, which he summarises to establish what is probably the main object of his history, the high position of the Abbey of Westminster, and particularly its independence of the See of London, and as to which he says:—"Nunc ergo quia locus iste a tantis nobilibus et sanctis viris, ut praedicitur, dedicatur, honoratur et dotatur, insuper libertatibus, dignitatibus et privilegiis roboratur; et quia ex primitiva fundatione locus iste est regiae consecrationis, regum sepultura, repositoriumque regalium insignium; caput Angliae merito diademaque regni ab antiquo nominatur."

Of the privileges appertaining to the Abbey it would seem that the tithe of the salmon caught in the Thames "a ponte de Stanes usque ad Yenlade ultra Gravesende" (from Staines bridge to Yantlet Creek) was highly valued, and FLETE devotes considerable space to the upholding of this right. The good monks, however, do not seem to have had all their own way in this matter, for the fishermen were offered quaint rewards for bringing in the salmon, being credited with so many candles as given to the church, and permitted to dine from the prior's table when the fish were eaten. There were disputes, too, with the Rectors of Wandsworth, Battersea, Chelsea, and Rotherhithe which led to arbitrations and compositions. Then comes a disquisition on the habits of the salmon and the derivation of its name "salmo a saliendo naturaliter nomen accepit."

Leaving the subject of salmon, FLETE gives an account of the relics and indulgences that helped to make the fame of his Abbey; then his history continues with the lives of the abbots, which are interesting reading, though the editor is at present unable to vouch for the authenticity or to correct the errors of his author. FLETE seems, however, to have been careful to have some authority at least for his statements, and to have avoided going to his imagination for facts necessary to render his history apparently complete, for he says, speaking of the unknown dates of the earlier abbots, "mallem igitur ista sub dubio relinquere quam aliquid mendaciter et sine causa fingere." One of the most interesting details in this part of FLETE'S writings is the reference to the two curtains or dossals that Abbot RICHARD DE BERKYNG (1246) gave to the choir, the inscriptions on which Dean ROBINSON quotes at length from a manuscript found at Gonville and Caius College, Cambridge. The thanks of all Englishmen are due to Dr. ROBINSON for making accessible the history by JOHN FLETE of our national church, the "caput Angliae," and we trust that the Dean may find time and opportunity to further extend his researches until he is able to decide whether FLETE or WIDMORE is right on the points as to which they disagree.

* *The History of Westminster Abbey.* By John Flete. Edited by J. Armitage Robinson, D.D., Dean of Westminster. (Cambridge: University Press. 5*s.* net.)

COMPETITION FOR HOSPITAL AT MOLESLEY.

WE should advise architects not to start on their drawings for this competition, as from the nature of the conditions we think it highly probable that the Competitions Committee of the Royal Institute will disapprove and bar the competition.

The hospital is to be quite a small one, two blocks of six beds each and administration block with bedrooms for a staff of six, laundry, mortuary, &c.

The remuneration is to be 4 per cent. on the architect's estimate, or the accepted tender, whichever is lower, and "should quantities be deemed desirable" by the Urban District Council, "they will allow a further 1 per cent."

No assessor or professional adviser is even suggested, as "the Council reserve to themselves the right to adjudicate upon the plans submitted." These are to be sent in by June 1 next "under motto," but there are no particulars given as to what they are to be, or to what scale they are to be drawn.

ARCHITECTURE: ITS TRUE PRINCIPLES.—IX.

By R. OWEN ALLSOP.

BALANCE.

NOW, if we turn to the subject of balance as distinct from pure symmetry, we open up an easier field for dissertation. Here, in the organic world, we see everywhere a balance of parts. The leaf or flower may not of itself be perfectly symmetrical, but it will be in more or less perfect balance. A tree is perhaps very unsymmetrical, but the arrangement of component masses gives a balance of parts that equally satisfies the eye.

Symmetry may be termed rigid justice—conformable to the principle of an eye for an eye. Balance, rather that of an eye for x pounds. In symmetry the scale will be equally loaded—the pound of gold on either side; whereas the idea of balance—in art matters—might be expressed by an arrangement whereby there is a sovereign's worth either side, but on the one side it is gold, and on the other silver or copper. "Symmetry" understands exact equality—substance, shape, and size.

Thus, in architectural matters we may balance a plain mass with one that is smaller but worth more by reason of the labour bestowed on its enrichment. No balance can result in two similar things the one smaller than the other. Of two western towers, if one were smaller than

Digitized by Google

the other we would not have any sense of balance or justice, but the arrangement and form and enrichment of the smaller may make up for its lack in bulk.

Symmetry appeals to the eye, balance to the understanding, the two terms being used in the art sense. Symmetry supposes—indeed, necessitates—an actual, supposed or imagined, axis or central point—that is, an axis or centre mathematically equal in distance from all corresponding parts of the two halves. If the symmetrical object has not a visible axial line or point, it has an imaginary one, such as in a vase, and generally such as may be produced by the revolution of outline round an axis. The eye must seek an axis, as in the case of a composition having wings, the centre by the eye is sought; for, as we have endeavoured to show, two objects, unless connected by a third, cannot form anything but two individual, unrelated units.

The Axial Line.

From what we have considered relative to symmetry and other kindred subjects, we must conclude that in all matters of architectural composition the question of axis, actual or understood, is of the first importance. Practically we know, the whole of design is based on axial lines, even if only constructive, and not appearing actually in the design. From centres we set out widths, measure distances, set our large parts as well as small. The axis of superficial and solid figures may be compared to the central idea, motive or main purpose in other things. Every composition in any art requires first its central idea or main theme, and so in the parts forming this whole composition there is need of actual or an inferred axis. Without such there is no unity, and without unity no individuality. The main effect of symmetry and axial design tends towards the producing of oneness in the whole, and as in life so in architecture, the strength of the community is the sum of strengths of component individuals, and with decay in the individual comes decay in the community. An ellipse may be constructed to contain the area of a given circle. The one is relatively diffuse, the other compact, and compactness is unity, unity is individuality, and strong individuality means force as distinct from that which is feeble, diffuse and scatter-brained. In like manner the contents of a cube may be contained in a parallelopiped. The one is compact, the other diffuse.

It will be seen that symmetry concerns one object—balance concerns two. We employ the terms on their accepted art sense. Symmetry *makes one*; balance makes two (or puts two) *at one*—that is, brings two into harmonious relation—smoothes out antagonistic differences, adjusts conflicting claims. The distinction is important as enabling a clearer idea to be obtained of the relative value of the two terms.

Symmetry of Unity and of Multiplicity.

We cannot give too much attention to the question of exact symmetry, its position in design. We see it to be at once the simplest method of producing ornamental effect and the most erudite if attempt is more to fully explain its whole significance and bearing. The least-cultured housewife arranges the "ornaments" on the parlour mantelshelf in symmetrical array. The clock or other feature considered as best and most imposing is placed in the centre, and the vases on either side must be in pairs—two small ones either side, two large flanking vases.

How universally this instinct is shown indicates some vital and quite sound principle. It is by no means to be dismissed as the crude ideas of uncultured taste. The truth lies deeper. The sense of order that arises from the centre-and-wing arrangement, being so universal, is to be looked for in some great fundamental principle. The idea of the arrangement of the mantelshelf ornaments is first the centre. This is evidently as it should be, and is simply a concrete demonstration of the appreciation of the principle of a central idea or theme in any work.

Whether the symmetrical object be an individual, indivisible unit—as a sphere, heart or trefoil—or a multiplicity of units—as a building, the idea of centrality, condensation, oneness, as contrasted to independence, diffuseness and manifoldness in the idea (apparently) upon which the principle of symmetry rests; for although in the plane representation of the heart form there is no obvious central axis, it is understood; and, more than this, the oneness of the form is derived from symmetry. We have seen that in a composition of centre and wings, the wings always predicate the centre and must, if not thus subordinate, at least always have reference to the centre, either as servants, dependents or guardians. Every symmetrical object therefore challenges the eye to find a central idea, a form or axis; and we must conclude that in the heart or trefoil the centre is the conception of the form itself, and, in the building group, the central feature of the winged composition.

Symmetry of Parts in Asymmetrical Wholes.

From the critical observation of various satisfactorily executed works of architecture we may deduce a general rule that though symmetrifying long elevations is a vain and objectionable practice, the smaller parts—especially the ends of wings and projections—should be rigidly symmetrical. The bad "one-sided" effect of the transepts at Salisbury are an instance of the effect of neglecting this rule. And a further safe guide is to enhance by centre-and-wing principle (or other suitable means) the symmetry of such minor parts of a composition. Where exact symmetry is intended it

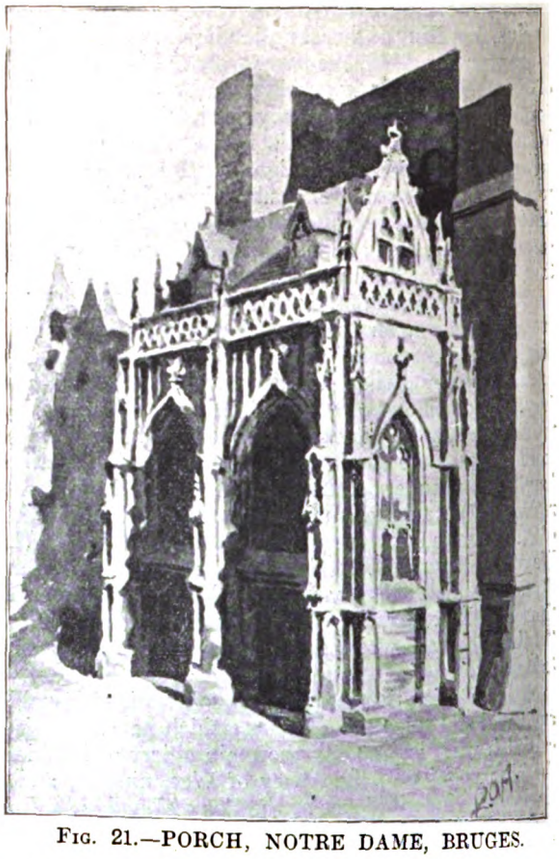

Fig. 21.—PORCH, NOTRE DAME, BRUGES.

should be complete and thorough in all details. The opposite to symmetry being asymmetry, the effect of bipartite design is to enhance—increase in value—by contrast, that which has not this regularity. In the instance of undesirable asymmetry that we have given—the ends of Salisbury transepts—we can see that this principle is just; for the want of regularity in the transepts agrees with that of the long side of the cathedral and no contrast is afforded. That which is embraced in the easy angle of vision (it might be suggested) should be symmetrical, hence the reasonableness of aiming at true (rigid) symmetry in the part.

All compositions wanting absolutely in symmetry of whole are bad unless upon a large scale—*i.e.*, such as the eye cannot examine except by moving the position of the spectator. It must be said that for small buildings

Digitized by Google

complete asymmetrical elevations are akin to patchwork composition. No effort of the architect can remedy completely the want of natural balance. The smaller the building the more desirable the symmetry, because we can so easily take in the whole in the normal usual angle at ordinary distances—even close at hand. Hence the poor effect of the average loosely-planned, scrappily-composed suburban house. While the large building suffers somewhere, if unnaturally symmetrified, the small one suffers from lack of symmetry. The cause is clear enough—the smallness of the object.

PLANNING, THE BASIS OF GOOD COMPOSITION.

The need of axial planning—to produce grand monumental architecture—is apparent. The axis induces symmetry. The same plea for symmetry in the composition may be made for symmetry in plan—that it necessitates thought in arrangement, as distinct from the thoughtless aggregation of parts that arises from the patching method. The materialised imaginary axis is the long imposing roof line, the impressive corridor, the massive balanced grouping in place of petty agglomeration of main parts of all sizes and shapes, jutting out here and there without any reason other than that the designer had no thought and no skill to arrange a definite scheme with definite aim.

The difficulty—and hence the scope—of architectural design resides in the manifold requirements to be ful-

FIG. 22.—THE NEST, ORPINGTON.

filled, practical and æsthetic; but we are now principally concerned with planning as the fundamental basis of architectural massing. The long nave roof has its co-relative indication on the plan. The central tower, the centre and wings of the façade are all indicated by the plan and must have some definite relation to this. A good architect can see at a glance the capabilities of a plan to afford scope for composing, and dignified, or at least interesting grouping. It is evidently impossible to produce noble effects, or even pleasing effects, on an ignoble plan. Architecture being a matter of three dimensions, and two of these referable to the plan, we might be tempted to say that two-thirds of architectural design rests in the plan. We all know by experience that no headway can be made with any composition, even if generally grasped by the mind's eye, until the ground, or main, plan is absolutely settled. This consideration will sufficiently stop any possible criticism that composition *per se* is not wanted in architecture so long as we are honest, simple, and structural, for if massing and grouping are based on the plan, they are solid attributes of design requiring study, since they are practical matters the offshoot of other practical considerations. Not a line can be changed in the main walling without affecting the grouping—unless, indeed, the whole affair is a make-believe, with steel girders destroying the truth of the work. Unless the component masses definitely refer to the plan, architectural composition becomes a sham.

Nothing is more definitely one in composition than a simple cathedral. The base of the plan, spiritually and practically, is the cross. The essence of the cross resides not in its arms but the actual crossing. Hence if the two western towers refer to the west gable—as we have seen—and this refers to the nave, and the junction of the nave and transepts marked by a bold tower, this latter becomes properly the dominant object, and indicates the actual crossing of the cruciform plan of a building suited to a religion based upon certain belief primarily associated with a simple cross. Hence in cathedral building for Christian worship the central tower is justified on all points by reasonable arguments. It is not in reality the dominating motive, which is the crossed plan, but it indicates this, and so is subordinate to the general idea.

Taking figs. 21 and 22 to represent respectively examples of symmetry of front and side and absolute asymmetry, the effect of the two masses is no doubt primarily due in great measure to this regularity and irregularity of composition. Yet most critics would pass over the fact. The old "Nest," it may be observed, was recently pulled down. The drawing was made after a portion of the building was removed, and the effect of this alteration was to create the unbalanced appearance evidenced in the rough sketch.

(*To be continued.*)

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

THE annual general meeting of the Royal Institute was held on Monday last, Mr. Leonard Stokes, Vice-President, in the chair, when the report of the Council for the official year 1908-9 was submitted and, after discussion, adopted.

The report states that since the publication of the last annual report the Council have held nineteen meetings, of which the Council elected in June last have held sixteen. The following committees appointed by the Council have met and reported on the matters referred to them:—Competitions, prizes and studentships, finance, sessional papers, premises, professional questions, Board of Professional Defence, Board of Examiners, Fellowship drawings, charter and by-laws revision, town planning, exhibition of architecture and decorative arts.

The losses by death have been as follows:—Fellows.—Cole Alfred Adams, Ibrahim Shaik Daúd Ahmadi, Alfred Darbyshire, Herbert Davis, William Milner Fawcett, Leslie William Green, Edward Augustus Gruning, Lewis Henry Isaacs, Henry Hill McConnal, James Neale, Francis Haslam Oldham, Edward Augustus Ould, Alfred Henry Paget, Hugh Stannus, John James Stevenson, Frederick Todd, Benjamin Woollard. Retired Fellows.—David Gostling, John Holden. Associates.—Ernest Carritt, Albert Edward Gough, Horace Moger, John Peter, William Candler Reed, Francis Adams Sprules, Isaac Steane, Charles Thomas Whitley. Hon. Corr. Members.—Arnold Guldenpfennig, Alfred Nicolas Normand.

Obituary notices of some of the above have appeared in the *Journal*.

The Royal Gold Medal was awarded last year to M. Honoré Daumet in recognition of his executed works as an architect and for his distinguished services in the cause of architectural education. M. Daumet received the medal in person at the general meeting on June 22, 1908. It has been decided to award the medal this year to Dr. Arthur John Evans, in recognition of the eminent services he has rendered to the history of architecture by his distinguished work of exploration in Crete. His Majesty the King has graciously signified his approval of the award.

The following tabular statement shows the present sub-

Digitized by Google

scribing membership of the Institute compared with that at the corresponding periods of 1907 and 1908:—

Year.	Fellows.	Associates.	Hon. Associates.	Total.
1907 . . .	862	1,254	46	2,162
1908 . . .	906	1,288	45	2,239
1909 . . .	888	1,344	46	2,278

During the official year since the last annual general meeting nine Fellows have been elected, eighty-two Associates, and one Honorary Associate.

The Progressive examinations were held in June and November 1908. The Preliminary was held in London, Birmingham, Bristol, Cardiff, Glasgow, Leeds, Liverpool, Manchester and Newcastle-on-Tyne; the Intermediate in London, Bristol, Cardiff, Glasgow, Leeds, Liverpool, Manchester and Newcastle-on-Tyne. The Council desire to record their thanks for the valuable services rendered by the hon. secretaries and examination committees of the various allied societies. The Final and Special examinations were held in London, and Special examinations for Colonial candidates were held in Melbourne and Toronto, when seven candidates were examined and five passed. The results are shown in the following tabulated form:—

	Admitted.	Exempted.	Examined.	Passed.	Rejected.
Preliminary examination	335	68	267	198	69
Intermediate examination	338	10	328	155	173
Final and special examinations	237	--	237	79	158

The total number of candidates was 910. The number of probationers now stands at 2,923, and of students at 961. The Council again have reason to regret that so large a number of students remain on the list without proceeding to the Final examination.

The Special examination for Colonial candidates will be held this year at Johannesburg, Sydney and Toronto.

The Ashpitel Prize was awarded to Horace James Ash, who passed the Final examination in November 1908.

The Council desire to thank the Board of Examiners for the continuance of their invaluable services.

The statutory examinations, qualifying for candidature as district surveyor in London, and for candidature as building surveyor under local authorities, were held in London in October 1908, when eleven candidates presented themselves. Certificates of competency to act as district surveyors in London have been granted to Frederick William Charles Barker, Alfred Ernest Biggs (A.), Henry Thomas Bromley (A.), Richard Thomas Grove, George Arthur Turner and William Ernest Watson (A.), and a certificate of competency to act as building surveyor under local authorities has been granted to George Arnall.

The deed of award of the various prizes and studentships was presented to the Institute at a general meeting on January 18, 1909. At the presentation of prizes on February 1, 1909, an address to students was delivered by the President, and a criticism of the work submitted was read by Mr. Paul Waterhouse (F.). An exhibition of the drawings was held from January 19 to 30 in the Gallery of the Alpine Club, and was visited by 1,332 persons. A selection from the prize drawings is now being sent the round of the allied societies.

On June 23 the annual dinner of the Institute took place at the Whitehall Rooms. The Institute was honoured on this occasion by the presence of M. Honoré Daumet (Royal Gold Medallist of the year), the Hon. Sir Schomberg McDonnell, K.C.B. (Secretary of H.M. Office of Works), the Chairman of the London County Council, and other distinguished guests.

"At Homes" were given by the President on April 28, 1908, when a selection of drawings and photographs representative of the executed works of the late Mr. E. W. Mountford were exhibited; and on February 8, 1909, when an exhibition was held of the work resulting from the tours of some of the travelling students of 1907 and 1908.

Since the issue of the last annual report the following sessional papers have been read before the Institute:—May 23, 1908, "The Architecture of the Bridges of London," by Professor Beresford Pite; November 16, "The Development of House Design in the Reigns of Elizabeth and James as Illustrated by Contemporary Architectural Drawings," by J. Alfred Gotch, F.S.A. (F.); December 14, "The Elements of Design in Internal Decoration," by T. R. Spence; January 18, 1909, "Public Abattoirs," by R. Stephen Ayling (F.); February 15, "Town and Country: Some Aspects of Town-planning," by H. V. Lanchester (F.); March 15, "American Architecture: with especial reference to work at Washington," by Francis S. Swales; March 29, "British Sculpture of To-day," by Marion H. Spielmann, F.S.A.; April 19, "The Architectural Work of the London County Council," by W. E. Riley (F.), architect of the London County Council.

The most important event in the history of the Institute during the year was the granting by His Majesty the King of the new supplemental charter in the month of December. The new by-laws to be applied for under the new charter are now in course of preparation by the Council, and will be submitted to the general body for discussion and approval at an early date.

During the course of the year the Transvaal Institute of Architects and the Architectural Institute of Canada have been admitted to alliance with the Royal Institute. The town-planning committee have carefully followed the progress of the Housing and Town-Planning Bill now before Parliament, and have secured the addition to the Bill of an amendment giving to architectural bodies a locus standi as "persons affected" at inquiries into town-planning schemes held by the Local Government Board. They have also promoted the formation of local town-planning committees by the allied societies, and they are continuing the investigation and study of the problems of town planning.

The Building Act amendment clauses of the L.C.C. (General Powers) Bill, 1909, have been considered by the Council as well as by the practice and science standing committees, and vigorous action has been taken, and is still being continued, with the object of securing such alterations in these clauses as will bring them into conformity with the general opinion of the architectural profession. The views of the Council upon the matter were expressed in a resolution which was forwarded to the chairman of the London County Council (*Journal*, January 23, 1909), and in a letter from the President of the Royal Institute to the chairman of the London County Council (March 5, 1909).

The eighth International Congress of Architects (Vienna, 1908) was well attended by British members. The Institute was represented by Mr. Leonard Stokes and Mr. John W. Simpson. The British contribution to the exhibition of architectural works consisted of a representative collection of photographs of recent English domestic work organised by the British section of the permanent committee. A review of the proceedings of the Congress, by the librarian of the Institute (under whose supervision the British exhibit was arranged), appeared in the *Journal* for June 6.

By the courtesy of the French Ministry of Fine Arts and of M. Jean Hulot, the Council were enabled to demonstrate to English students the methods and achievements of French prizemen in architecture by the exhibition in London last July of M. Hulot's Prix de Rome drawings illustrating his restoration of the ancient Greek city of Selinus. The exhibition, which lasted a fortnight and created much interest, was held at the gallery of the Royal Society of Painters in Water-Colours. A paper descriptive of the work, kindly contributed by M. Gustave Fougères, Professor of Greek Literature at the Sorbonne, and translated by Mr. John W. Simpson, was delivered at the formal opening of the exhibition.

The resignation by Mr. Alexander Graham of the post of hon. secretary of the Royal Institute after ten years of office affords the Council an opportunity of placing on record their profound sense of the great services which Mr. Graham has rendered to the Royal Institute during the whole of this period, and of the untiring devotion which he has displayed in the exercise of the important duties of the hon. secretaryship.

Since the issue of the last annual report the Council have made the following appointments:—

The Institute representative on the Council of the National Trust for Places of Historic Interest or Natural Beauty, Mr. W. A. Forsyth.

The Institute representative on the Engineering Standards Committee Sectional Committee on "Bridges," Mr. Edwin T. Hall.

The Institute representative on the special committee of the International Drawing Congress for the unification of signs and symbols used in drawing, Mr. Francis Hooper.

The Institute representative at the annual convention of the Institute of Architects of Canada, Mr. F. S. Baker.

The Institute representative on the Royal Commission on the Preservation of Ancient Monuments in England, Mr. Leonard Stokes.

The Institute representatives on the joint committee on water regulations, Mr. George Hubbard, F.S.A., and Mr. H. V. Lanchester.

The Institute representative on the Tribunal of Appeal, Mr. John Slater.

Digitized by Google

The Institute representative at the Local Government Board inquiry on Poor-law institutions, Mr. Edwin T. Hall.

The Institute representative on the Senate of the University of Sheffield, Mr. J. Alfred Gotch, F.S.A.

The Institute representatives at the conference called by the superintending architect of the L.C.C. to consider the questions raised in Part 5 of the L.C.C. (General Powers) Bill, 1909, Mr. Edwin T. Hall and Mr. John Slater.

The Institute representative on the Court of the University of Liverpool, Sir William Emerson.

The Institute representatives to give evidence before the Board of Trade Committee on Artistic Copyright, Mr. John Belcher, R.A., and Mr. John W. Simpson.

Since the issue of the last annual report the Council have made the following grants:—Architectural Association, 100*l.*; Architectural Association Sketch Book, 25*l.*; Architects' Benevolent Society, 125*l.*; British School at Rome, 21*l.*; W. G. Hunt (Acton competition), 100*l.*; Royal Architectural Museum, 21*l.*; Sheffield Society, 20*l.*

The following have been the President's appointments to assessorships during the official year:—

Aberystwyth .	National Library .	Professor Reginald Blomfield, A.R.A.
Bangor . .	Normal College . .	Mr. John W. Simpson.
Bury . .	Elementary Schools .	Mr. John W. Simpson.
Colchester .	Technical Institute .	Mr. Paul Waterhouse.
Hull. . .	Training College. .	Mr. John W. Simpson.
Ilford . .	Emergency Hospital .	Mr. H. Percy Adams.
Islington . .	Vagrant and Receiving Wards . . .	Mr. Lewis Solomon.
Kirkwall . .	St. Magnus Cathedral Restoration . .	Mr. John James Burnet.
Reading . .	County offices . .	Mr. Mervyn Macartney, F.S.A.
Shrewsbury .	Schools . . .	Mr. Henry T. Hare.
Stoke-on-Trent.	Town hall Extension .	Mr. Leonard Stokes.

Copies of the "Regulations" have been sent to the promoters of the following competitions, together with letters requesting that a copy of the conditions be sent for the Institute Library. In cases where the conditions have been unsatisfactory, letters urging modifications have been sent to the promoters:—

Aberystwyth, National Library.
Appleby and Tebay, Elementary Schools.
Astley Bridge, Branch Public Library.
Banbury, Elementary School.
Bellshill, Bothwell, Council Chambers.
Beverley, Baptist Church and Schools.
Blackpool, Central Public Library.
Bournemouth, Branch Library.
Brighouse, Secondary Schools.
Brighton, Assistant Medical Officer's Residence.
Bristol, Royal Infirmary Extension.
Bury, Elementary School.
Bury, Secondary School.
Cardiff, County Hall and Offices.
Cleckheaton, Secondary and Technical School.
Colchester, Technical Institute.
Disley, Council Schools.
Dolgelly, Free Library.
Eastleigh, Concert Hall.
Elland, Mixed Schools.
Glamorgan, County Hall.
Great Lever, Branch Public Library.
Gorseinon, Church.
Grimsby, Town Hall Extension.
Guernsey, County Hospital.
Halliwell, Branch Public Library.
Liscard, Library.
Manchester, Congress Church House.
Merthyr Tydfil, Y.M.C.A. Building.
Middlesbrough, Library.
Moseley, Mixed School.
Motherwell, Parish Council Chambers.
Nantwich, Council Schools.
Pontardawe, Guardians' Offices.
Pontypridd, Union Offices.
Reading, County Offices.
Romford, School.
Rowley Regis, Public Libraries.
Shrewsbury, Secondary Day School.
Southbank-in-Normanby, Town Hall.
Stockport, Schools.
Swansea, Cottage Extension.
Swinton, New Schools.
Truro, County Offices.
Tiverton, Higher Grade Schools.
Whitehaven, Schools.

The Council by publication in the *Journal* and the professional Press have advised members of the Institute not to take part in the following competitions:—Blackpool Central Public Library (advice subsequently withdrawn), Nantwich Council schools, Southbank-in-Normanby town hall, Stanley District Council offices.

The Council have the pleasure to report the continued financial prosperity of the Institute, and to point to the balance of 1,841*l.* 14*s.* 4*d.* of income over expenditure. The sum of 4,213*l.* 19*s.* 10*d.* has been invested, as against 3.035*l.* 19*s.* 7*d.* last year. The invested capital is now over 26.000*l.* The statement of income and expenditure and the balance-sheet for the year ending December 31, 1908, and the estimate of income and expenditure for the current year, are appended to this report.

The Board of Architectural Education reported:—

The Board have held five meetings since their last report.

The list of books recommended to students referred to in the last report has now been issued. The method of teaching architecture in schools subsidised by Government has been considered by the Board, and a committee has been appointed to draw up a memorandum on the subject for discussion by this Board before communicating thereon with the Board of Education. The attention of this Board has been directed to the fact that the L.C.C. School of Building at Brixton now includes a Day Technical School, admission to which is restricted to boys between thirteen and fifteen years of age who have passed the sixth standard of an elementary school, and the Council of the Institute, on the recommendation of the Board, have communicated with the London County Council suggesting that while training given in this school may be most useful for those intended for the building trades, it differs materially from that recommended by the Board for the education of architects. The question of the advisability of recommending the Council of the Institute to grant exemption under certain conditions from the Final examination to students of schools of architecture at the Universities of Liverpool, Manchester and Sheffield; the Architectural Association, London; King's College, London; and University College, London, has been before the Board and has been referred to a committee appointed by the Council of the Institute to consider the whole subject of the Institute examinations.

The following modifications in the Intermediate and Final examinations recommended by a joint committee of the two Boards will come into operation at the summer examinations this year:—

The Intermediate.

The following specific subjects will be omitted from this examination in future:—

1. Classic ornament.
2. The characteristic mouldings and ornament of each period of English architecture from A.D. 1000 to 1550, with their application.
3. The orders of Greek and Roman architecture; their origin, development and application
4. Outlines of the history of Mediæval and Renaissance architecture in Europe.

Instead of the above, two papers will be set on (1) the General History of Architecture; and (2) the Purpose of Architectural Features in Relation to the Buildings in which they occur.

Answers to be accompanied by explanatory sketches.

The Final and Special.

The following specific subjects will be omitted from the examinations in future:—

Subject 11.—The Principal Styles of Architecture: their Features, Mouldings and Ornament. (i) The Characteristic Mouldings, &c., of the Special Style selected by the student; (ii) The Characteristic Mouldings, &c., of the Principal Styles of Architecture.

Instead of the above the following papers will be set:—

Morning.—The Principles of Architecture: their Theory and Application. Illustrated by drawings.

Afternoon.—A written thesis. Illustrated by sketches.

The amended report of the Diploma in Architecture Syndicate at Cambridge University was considered by a committee of the Board, who suggested certain modifications therein, and on the recommendation of the Board the Council forwarded the said suggestions to the Syndicate.

During the past year the Visitors appointed by the Board have visited the Architectural Association Schools; King's College, London; University College, London; Liverpool, Manchester and Sheffield Universities. The Visitors have reported satisfactory progress in these schools.

THE ARCHITECTURAL ASSOCIATION.

THE concluding meeting of the present session of the Association was held on Friday evening last at Tufton Street, Westminster, Mr. Walter Cave, president, in the chair.

Messrs. B. H. Jackson, S. H. Reeves, F. C. Anson, J. Early Smith, M. C. Broad, T. F. H. White and C. J. Esch were elected members.

The HON. SECRETARY announced that the annual dinner would be held on May 12 at the Georgian Hall, Gaiety Restaurant; he also reminded members of the first summer visit on May 15 to Maidenhead.

On the motion of the PRESIDENT votes of thanks were passed to Mr. John J. Burnet for his donation to the library of Messrs. Collignon and Pontremoli's book on Pergamos; to Mr. James Williams for a most generous gift of two working drawings by the late George Devey; and to Messrs.

Digitized by Google

J. G. N. Clift and A. C. M. Edwards for a number of lantern slides.

The PRESIDENT then read the scrutineers' report on the election of officers for session 1909-10. The report stated that 350 voting-papers were received—a decrease of fifty-five on the number returned last year—and that three were rejected as invalid.

The results were as follows:—President, Mr. Henry Tanner; vice-presidents, Messrs. F. Dare Clapham and C. Wontner Smith; ordinary members of Council, Sir A. Brumwell Thomas, Messrs. Gerald C. Horsley, Arthur Keen, F. Winton Newman, R. Frank Atkinson, Horace Field, G. Gilbert Scott, Baxter Greig, Herbert A. Hall; ex-officio member of Council, Mr. Walter Cave (retiring president); hon. treasurer, Mr. Henry T. Hare; editor of the *Architectural Association Journal*, Mr. G. L. Elkington; hon. librarian, Mr. Percy May; hon. secretaries, Messrs. Maurice E. Webb and Edwin Gunn; hon. assistant librarians, Messrs. W. D. Cathcart and A. J. Perrin.

A hearty vote of thanks was accorded to Messrs. R. J. Buck, W. B. Dukes, G. D. G. Hake, R. Lowry, H. L. Samson and E. J. Tanner for acting as scrutineers.

It was also announced that the A.A. Athletic Club meeting would be held on Saturday afternoon, June 5, at Stamford Bridge.

Mr. C. WONTNER SMITH read a paper, illustrated by sketches and lantern views, on—

Bruges and the Neighbourhood.

The subject of my paper this evening, he said, was suggested by the visit paid last year to Belgium by the Architectural Association on the occasion of our annual excursion, when a very enjoyable week was spent in visiting the principal towns in the vicinity of Bruges, which we made our headquarters.

These old Flemish cities are, of course, well known to many of you. Belgium is easily accessible, and, possessing many architectural attractions, forms a splendid ground for study. To the majority, therefore, I can only recall scenes already familiar, but those who have not been as yet to Belgium may find a short description of the principal cities of some interest, and I propose to sketch briefly the outlines of their history, mentioning the best-known buildings and architectural features, merely giving you my impression of them, with no attempt at an exhaustive criticism, which I do not feel competent to undertake were there even sufficient time at my disposal for the task. Interesting as they are, it is not within the scope of this paper to deal with the origin and development of these cities, which in the Middle Ages formed the great commercial centre of Northern Europe, but before proceeding further with the subject, I should like to mention a few of the more important facts concerning their earlier history. Belgium was originally peopled by a race of Celtic origin, and they were the last of the northern tribes to withstand the Roman invaders, although eventually crushed. After the power of Rome was finally broken, the first Flemings descended on the shores of Northern Europe. These men were of the same race as our own Saxon forefathers, and men of the same spirit, hating slavery and oppression, and content only so long as they retained their freedom. They were quick to resent any attempt to reduce them to serfdom, and consequently the country during the Middle Ages was the scene of perpetual warfare. They alone among the nations of Europe succeeded in retaining any degree of independence.

There is little to learn from history about this part of Europe from early times till the ninth century, when Baldwin of the Iron Hand, the first Count of Flanders, took up his residence upon a small island situated between the rivers Boterbeke and Roya. This place was Bruges, destined in after years to become one of the most important cities of the Middle Ages. Baldwin was the real founder of Bruges, although it existed before his time, probably in the form of a fortified camp. The old Bourg was pulled down, and Baldwin erected a new fortress on the site now occupied by the Hôtel de Ville and Palace of Justice. Around this was grouped Baldwin's own residence, the chapel, the court prison, and on the north side the sanctuary, in which were placed the relics of St. Donatian, which had been given to him by the Archbishop of Rheims. Of the Bruges of Baldwin's days, all that now remains is the crypt underneath the Chapel of the Holy Blood, situated on the west side of the Hôtel de Ville. The two streams by which Bruges was built still exist; the Roya runs in the same course as it did then, but it has been tunnelled over and built upon in the course of the intervening centuries. The Boterbeke has long since been diverted, and now only skirts the town. Bruges passed through many vicissitudes between Baldwin's days and the fifteenth century, when it reached the summit of its prosperity. Apart from its other claims, the city must have special interest for us. Its rulers have been closely associated with those of our own country, and many well-known figures of English history have had reason to be grateful for the shelter obtained within its walls—the wife of Canute the Great, the sons of Earl Godwin, Hereward the Wake, St. Thomas à Becket, and in the seventeenth century Charles II., to mention only a few of the number who it is known resided in, or at any rate, visited the city. I will not, however, trouble you with a lengthy account of its history through the Middle Ages. The source of its prosperity was partly due to its geographical position and extensive trade. *(To be concluded.)*

ILLUSTRATIONS.

WELLINGTON COLLEGE.—PRINCIPAL FRONT TO GREAT HALL—THE GREAT HALL.

THESE buildings were carried out in 1906-7, and were opened by H.M. the KING on June 18 in the latter year. They consist of a dining-hall capable of seating 350 boys; an eastern wing containing a mess for the masters consisting of ante and common rooms, billiard and reading rooms, spare bedrooms, &c. The western wing contains the matron's department, with linen stores, packing and unpacking rooms, and sewing rooms, together with quarters for the matrons and their maids. On the north side are the kitchens, sculleries, larders, and other offices. A corridor or cloister runs along the front or south side of the building, and connects the new block with the Combermere and Hardinge dormitories on the east side and with the main college buildings on the west. The ground available for the building was strictly limited on all four sides, and consequently certain rooms and offices which would otherwise have been on the ground floor were of necessity relegated to the basement—*e.g.*, the servants' hall, steward's room, and stores and offices, &c. The dining hall is covered with a high-pitched roof of steel construction, ceiled internally with an elliptical plaster ceiling, and the walls are panelled in oak for some 8 feet in height. Fletton bricks were used in the construction of the walls, the facing externally being in red bricks. Monk's Park Bath stone was used for all external stonework. The whole of the roofs are covered with green Westmoreland slates. The contractor was Mr. J. B. SEWARD, of Wokingham. The design was the result of a competition limited to four architects, the successful competitor being Mr. CHARLES J. BLOMFIELD, from whose design and under whose direction the work was carried out.

HOWE COOMBE, WATLINGTON.

THE illustrations of above, which we publish to-day, are the architect's first rough studies for the house, which in a rather more extended form was built in 1907-8 for A. H. PAWSON, Esq. The house is externally of flint and brick, with tile roof, and the windows have metal casements with leaded lights. The architect is Mr. T. FRANK GREEN, A.R.I.B.A.

ST. SWITHUN'S, HITHER GREEN, S.E.—INTERIOR, LOOKING EAST.

THIS church was one of four built by the Lewisham Church Extension Association; the nave and aisles were built in 1892 by Messrs. PARMENTER, of Braintree, Essex. The transepts, chancel, morning chapel, vestry, &c., were built in 1904 by Messrs. MAIDES & HARPER, of Croydon. The brickwork is all of Wrotham bricks, and the stonework of Bath stone. The whole of the stonework was limewashed on completion. The choir stalls and fittings generally are at present temporary. The architect was Mr. ERNEST NEWTON, of 4 Raymond Buildings, Gray's Inn.

BISHOPSTONE CHURCH, WILTS.—SOUTH TRANSEPT.

THESE sketches by Mr. E. GODFREY PAGE speak for themselves as illustrating distinctive and typical examples of English church architecture.

SALISBURY CATHEDRAL.—INTERIOR OF NAVE.

THE history of Salisbury Cathedral is well known to all our readers, and Mr. E. GODFREY PAGE's sketch shows an architect's rendering of the design of the nave.

THE DANGERS OF BREEZE CONCRETE.*

(Concluded from last week.)

Breeze Sample No. 3.—Described as "coke breeze," consisted of coke and clinker, with a little coal. The coke varied from 2 inches diameter to fine dust. About 48 per cent. passed through a ¼-inch sieve; the remaining 52 per cent. sorted over gave 40.6 per cent. coke, 8.6 per cent. clinker and 2.64 per cent. coal. These results were also mainly negative. The coal being such a small fraction, it was not possible to make such extended experiments as one would wish, but so far as they go they show that this particular coal—a species of anthracite—was practically harmless.

Breeze Sample No. 4.—Described as "furnace ashes." This sample was very damp when received, and had to be dried before it could be treated. About 26 per cent. passed through a $\frac{1}{10}$-inch sieve and 22 per cent. through a ¼-inch. The remaining 52 per cent. was sorted out into coke about 15 per cent., coal 1.5 per cent. and clinkers 35½ per cent. Each of these five fractions, tested with the two cements as before described, again gave practically negative results.

Breeze Sample No. 5.—Described as "gasworks clinkers," consisted of clinkers only, ranging in size from 4 inches diameter downwards. They were crushed to pass a $\frac{1}{20}$-inch sieve as before described, and tested in the same way as previous samples, but with negative results.

All the foregoing samples having given negative results, attention was next directed to samples of "breeze" which the contractors supplying them described as "sometimes used for floors, but which they neither used nor recommended"; Nos. 8, 9 and 10, moreover, were described as "such that would not be allowed by a clerk of works for fireproof flooring," but the author found them to differ very little indeed from the ingredients found in many samples of breeze concrete taken from important works.

Breeze Sample No. 6.—Described as "ashes or furnace refuse." About 21½ per cent. passed through a $\frac{1}{10}$-inch sieve and 15½ per cent. through a ¼-inch sieve. The remaining 63 per cent. after sorting gave roughly 34 per cent. coke, 27 per cent. clinker and 1 per cent. shaley matter.

Treated as before, the results were again negative.

Breeze Sample No. 7.—Described as "ashes or furnace refuse." About 16 per cent. passed through a $\frac{1}{10}$-inch sieve and 17 per cent. through a ¼-inch sieve, the residue of 68 per cent. on the ¼-inch sieve giving 32 per cent. clinkers, 23 per cent. coke and 13 per cent. coal.

It will be noticed that this sample contains a considerable quantity of coal, whereas No. 6, a material described by the suppliers in exactly the same terms, contains none; this coal does not appear to have exerted any deleterious influence upon the specimens, probably due to its being of an anthracitic rather than of a bituminous nature, but this point will be dealt with more fully later on.

Breeze Sample No. 8.—Described as "sample of coal ash straight from furnace of paper-mills, burnt from coal only." This sample was greyish-white in colour, and contained a considerable quantity of clinkers; the clinkers being more or less friable probably accounts for the larger proportion passing through the sieves. About 43 per cent. passed through a $\frac{1}{10}$-inch sieve and 12 per cent. through a ¼-inch sieve. Of the 45 per cent. remaining, about 20 per cent. was clinker, 23 per cent. coke and 1½ per cent. coal. Although the specimens left entirely in air developed little or no expansion, all the fractions except the coke and clinkers showed rather marked expansion in water, the coal being very much the worst. Unfortunately the quantity of coal found was so small that it was only possible to try it with one cement, but with the other fractions the results obtained with the two different cements practically corroborate one another, although cement A develops rather more expansion in each case than cement B.

Breeze Sample No. 9.—Described as "sample of ashes dropped from the firebars of furnace from waterworks, from coal and coke." This sample was nearly all fine material, 42½ per cent. passing through a $\frac{1}{10}$-inch sieve and 31 per cent. through a ¼-inch sieve. Of the 26½ per cent. of material remaining on a ¼-inch sieve, 8.3 per cent. was clinkers, 7.3 per cent. coke, 7.48 per cent. coal, with a little ash and a few stones. The water-test bars from all the fractions showed enormous expansion, the ¼-inch, $\frac{1}{10}$-inch and the average expanding 4 or 5 per cent. within the first three or four days, and subsequently swelling so much as to break and render further measurements impossible. The coal fraction expanded 3 per cent. within a week, increasing to 4 per cent. in twenty-eight days, after which it appeared to remain practically constant. Several of the air specimens, more especially of the fine material passing the $\frac{1}{10}$-inch sieve, showed rapid expansion for the first day or two, and then remained practically constant, with, if anything, slight subsequent contraction. The results obtained with the two different cements were practically identical, and corroborated one another fairly closely. The special value of the results obtained with this particular sample of breeze is that it shows very clearly that some kinds of ashes and furnace refuse are even more dangerous than coal.

Breeze Sample No. 10.—Described as "rough ashes from furnace of electricity works from coal only." About 14½ per cent. of this material passed through a $\frac{1}{10}$-inch sieve and 30 per cent. through a ¼-inch. Of the remaining 55½ per cent., 43½ per cent. was clinkers, 5½ per cent. coke, 4½ per cent. coal and a few stones. Only the finer material passing a $\frac{1}{10}$-inch sieve developed any appreciable expansion—i.e. about ⅓ per cent.—which it attained in about a month, and thereafter appeared to be constant. Several of the other fractions showed measurable though negligible expansion, ranging from .002 to .09 per cent.

A noticeable feature of the foregoing experiments is that many of the specimens which showed very marked expansion when placed under water as soon as set, expanded very much less when left entirely in air. It therefore seemed a point worth determining as to whether exposure to damp or moisture would in any way affect these air-set specimens at the end of the three months' tests—i.e. after they had become thoroughly seasoned. One of the duplicate air bars from each series was therefore placed under water, the time elapsing between the date of moulding and placing under water ranging from 91 to 292 days. Immersion had practically no effect upon those specimens which had previously shown no expansion when kept under water, but caused almost immediate expansion of a very serious nature with those fractions of breeze which had previously developed expansion when placed under water in the first instance. This clearly shows that the expansive agent, whatever it may be, is more or less dormant in the dry air-set block, and only requires to become damped to constitute a serious element of danger.

Referring now to the chemical aspect of the question, it was intended when the experiments were first commenced not only to analyse each fraction of each sample, to ascertain if it contained any deleterious constituent, but also to analyse each mortar, both immediately after gauging and again at the end of the experiments, to try and ascertain if and when any expansion had occurred, whether there was any marked chemical difference between them which would enable the cause of the expansion to be detected, and thus serve as a guide in the investigation of actual cases of failure. After analysing some thirty-six samples with entirely negative results, this idea was abandoned as involving too prodigious an amount of labour without any likelihood of corresponding reward; seeing, however, that some of the coal fractions caused enormous expansion while others caused practically none, they were examined chemically, with the view of ascertaining the cause of this marked difference. The results showed that the coals from breeze samples Nos. 8 and 9 were highly bituminous, containing 35 per cent. and 33½ per cent. respectively of volatile matter, while those from samples Nos. 7 and 10 were more of the nature of anthracite, containing only 4 per cent. and 3 per cent. respectively of volatile matter. This indicates very clearly that bituminous coal is highly dangerous, while anthracite appears to be harmless. Apart from coal, the only analysis of the other fractions calling for comment is the fine material passing the $\frac{1}{10}$-inch sieve of sample 9, which was found to contain 3¾ per cent. of SO_3, which is doubtless partially responsible for the high expansion shown by this fraction, aggravated no doubt by the presence of some fine coal.

Taken as a whole the experiments as far as they go seem to point to the fact that as regards subsequent expansion there is not much danger to be apprehended from good clean coke or clinkers, or even anthracite coal, but that some kinds of ashes and furnace refuse are highly dangerous, while any considerable quantity of bituminous coal is absolutely fatal. One noticeable feature of the experiments, however, was that most of the coke breeze mortars had a tendency to more or less seriously attack the iron moulds in which the Bauschinger bars were made, causing them to rust during the short space of twenty-four hours between the

* A paper read before the Society of Architects by Mr. D. B. Butler, A.M.Inst.C.E., on April 22.

moulding of the specimens and their removal from the moulds; the author is unaware if such results have been found to any appreciable extent in actual practice, but samples of breeze concrete sent him for examination a short time ago showed distinct marks of considerable rusting having taken place where the concrete had been in contact with the rolled joists. If such prove to be the case, it might in the end prove a very serious matter, as affecting the life and strength of the steelwork.

Altogether the experiments previously described represent some two years' work, and include the preparation of about 300 testpieces, involving some 5,000 measurements, to say nothing of the sifting, sorting and preparation of the breeze samples; the author is only too conscious of the fact that they are far from reaching finality; indeed, they only touch the fringe of a wide field of research, in which there is a vast amount of work to be done; having ascertained, however, that certain materials constitute a serious source of danger, and probably account for many of the "breeze" concrete failures which he has met with, he trusts that the danger signals most unmistakably displayed by the foregoing researches may prove of value to his hearers and tend to prevent the recurrence of such failures in the future.

Since the inception of these experiments the following extract from the *Tonindustrie-Zeitung*, dated April 25, 1908, shows that the importance of the subject has at all events begun to be appreciated in Germany:—

"*Verwendung von Kohlenschlacke zur Herstellung von Beton.*

"Der Minister der Offentlichen Arbeiten hat am 25. März 1908 folgenden Runderlass an die Regierungspräsidenten versandt:—

"'Nach Anhörung des Deutschen Ausschusses für Eisenbeton empfehle ich, Ew. Hochwohlgeboren, die Verwendung von Kohlenschlacke zur Herstellung von Beton, des sogenannten Schlackenbetons, bezuglich der Ausfuhrung von Eisenbetonbauten allgemein, also auch fur die sogenannte Zugzone in Decken und Balken zu verbreiten. Die Verwendung der Schlacke zur Herstellung von sonstigem Beton, sogenanntem Stampfbeton, wird nur da zuzulassen sein, wo die Gefahr, die tragende Eisenteile mit derartigem Beton in Beruhrung kommen oder Menschen von herabfallendem Putzmörtel getroffen werden können, ausgeschlossen ist.'"

The purport of the above, somewhat freely translated, is as follows:—

"*Use of Coal Residues for Concrete.*

"The Minister for Public Works has on the 25th March 1908 issued the following circular, addressed to the Presidents of the Government:—

"'After having received the report of the German Board on reinforced concrete, I recommend the prohibition of the use of breeze as an aggregate for concrete for the erection of reinforced concrete buildings in general, also in ceilings and beams wherever tensile stresses may occur. The use of breeze for other kinds of concrete will only be admitted in such cases where there is no danger of its coming into contact with the supporting ironwork nor of people being hurt by the falling concrete.'"

Professor HENRY ADAMS, in proposing a vote of thanks to the author of the paper, said Mr. Butler was a well-known expert on all questions relating to cement, and therefore his opinion was authoritative and useful. There were many points in the paper that might be open to discussion. In the first paragraph the author spoke of the expansion of mass concrete causing failures. That is, he said, a very serious matter to architects when dealing with large floor spaces, as in warehouses, hospitals and other extensive buildings. The mischief is only partially prevented by the use of expansion boards, and although in some cases it has been found to be due to the cement, the author had shown them that it was undoubtedly due in most cases to the coke breeze. He thought he was justified in saying that reliance was placed upon the material in consequence of the report of the British Fire Prevention Committee that coke breeze could resist the action of fire so well, and architects had consequently used it largely. He personally was very doubtful at the time of the tests as to the accuracy of the experiments, for they were using a combustible material and expecting it to resist fire. The author in his paper gave an example of coke breeze concrete used for a boiler setting actually taking fire. The co-efficient of expansion of glass and cement were referred to. If the cement expanded so much more than glass, he would have expected to see the bottoms burst off the bottles; instead of that it seemed to be a small portion was broken off the side, and not so much at the end. The results generally showed that the expansion under water was negligible, and that air-set concrete contracted. One would have expected, however, a fireproof floor to expand rather than contract, whereas the small tests showed the opposite result. Further on in the paper it was shown that a test block set in air would be subject to expansion if it got moist, and the speaker inferred therefore that a fireproof floor would remain constant until moisture reached it, and he supposed it would contract again when the moisture left it. It was important to notice the remarks about the tendency of coke breeze mortar to cause rusting of the iron moulds. The Concrete Institute had that as one of the questions under consideration—the corrosion of metal in concrete—and the results of the experiments undertaken by Mr. Butler afforded some direct and useful evidence upon this point.

Mr. E. J. SADGROVE seconded the vote of thanks. The paper, he said, mentioned some instances of coke breeze being used as a fireproof material, but he had himself given up using that particular aggregate some years ago, for he had actually seen men engaged in the construction of a building in which it was employed using the material as fuel for cooking their dinners. He would not care, therefore, to use coke breeze for fireproof roofs or flats. One thing he could not understand was the fact that breeze was intended to be anything else but coke breeze, and it had always seemed to him that some other light material should be used.

Mr. H. G. BAMBER, referring to the analyses that had been given in the paper, said he had hoped, knowing of the considerable number of failures that had taken place when breeze concrete was employed that Mr. Butler would have been able to give some reasons, probably chemical ones, for the failures. He believed that a sulphur compound was present in the coke in combination with some other material in the form of sulphide, and any compound, either in cement or the aggregate used in the cement, which was of an unstable character and could form a compound when placed in the composition, was dangerous to employ as a building material.

Mr. MAX CLARKE, F.R.I.B.A., said he was not a chemist, nor was he a cement expert, but he was one of those unfortunate people who had had some considerable failures with coke breeze concrete, and he had seen in other cases worse failures than he had experienced. That was some years ago, and consequently he tried to find out what was the cause of failure. He went therefore to a gas works and made some investigations on his own account. He tried to find out what a great many architects did not know—the difference between "pan" breeze and "coke" breeze. His definition for "pan" breeze was the material which fell into the water pan under the furnace during the process of making gas, and he defined "coke" breeze as the material that was drawn from the retort after the gas was extracted. The results of his experiments seemed to confirm the remarks made by his friend Mr. Bamber as to the sulphur being at any rate one of the causes of expansion of concrete made with breeze. Since those experiments he had avoided so-called coke breeze. He did not agree with the speakers who stated that it was an inflammable material, because he was almost certain that it was not. He had in the office a sample of coke breeze that was experimented on at the British Fire Prevention Committee's station. It was in position underneath an iron joist, and was about 2 inches thick, and was subjected to more than 1,500 degrees Fahrenheit of heat. On the side which was in contact with the joist there was not the slightest difference. They found at those experiments that the coke breeze floors became as it were more incandescent than the other floors, but they did not show the slightest tendency to flame and the concrete in the centre was just as good as when first put up. Be it what it might that caused the expansion, he not being a chemist thought it was the sulphur, and he thought he saw on one of the bars shown on the screen certain white marks, and he believed that those marks were due to sulphide. He was personally indebted to Mr. Butler because that was the first time he had heard the matter thoroughly discussed publicly. He had himself been experimenting for years, and there were tests still in progress, but the results could not be known yet. The lecturer said that the expansions shown on the screen were negligible, but he maintained that that was not so. Suppose he said one had an expansion of a foot in a warehouse floor, say 100 feet long, the danger would be considerable, and even if the expansion was $\frac{1}{10}$ per cent. it would cause serious damage. He then drew the attention of the meeting to a drawing of a small strong room about 19 feet long and an average width of 6 feet; it had a coke

Digitized by Google

breeze roof 14 inches thick, and between the coke breeze and the wall was a 1¼ inch space all round. The walls were 14 inches thick with two courses of hoop-iron in each joint of the brickwork. At the end of nine months the detached end had expanded and cracked the walls to the extent of about ¾ inch. He had the case in his mind of a large warehouse about 150 feet long and 60 feet wide, and only one storey high. The people wished a floor put in about ten feet from the ground, and there were some small steel joists supported on longitudinal joists and stanchions. The coke breeze floor was isolated on two sides and one end, a 60 feet length sticking out. It was exactly 60 feet long when put up, and four months afterwards it was measured and found to be 60 feet 4 inches long. It was more or less cracked all over, and as it supported liquor tanks for a special purpose the floor was always more or less damp. Those experiments perhaps showed that once concrete became damped there was failure. He had, he said, put in concrete floors 150 feet long and they showed no cracks whatever. He had tried to get pure coke breeze, and found it was practically an impossibility. If they could have the coke breeze broken up and washed, he thought they would get more reliable material than that which at present went by the name of coke breeze, but even then it might not be reliable.

Mr. MARSH, of the Metropolitan Water Board, said he did not personally have large dealings with coke breeze. The structures he undertook were all of an engineering character in which harder and heavier aggregates were used in the cement work, but he wondered why destructor clinker was not tried. He had always known that concrete when set in air contracted, and set in water it expanded, and he was certain that any of the ordinary engineering aggregates with concrete, if set in air, would contract.

Mr. H. E. HAWKER said his experience of coke breeze had been contraction and not expansion. Floors and roofs made up of that aggregate served well for a certain time, six months perhaps, and then cracks became visible. To get over the difficulty he had used expanded metal, introducing it in the ordinary breeze floors. Bent wire round the joists was also a good method.

The CHAIRMAN, in putting the vote of thanks to the meeting, said it seemed to him the moral of the whole lecture was that when coke breeze was specified they should see that they got it, for they had seen by the results of the experiments that it was the materials which were not breeze that caused all the trouble. They had heard some remarks as to coke breeze not being a fire resistent. The diagram they had seen during the lecture represented experiments with very small samples, in fact, laboratory tests rather than practical ones. The British Fire Prevention Committee had tested a hut built of the material, subjecting it to fire for more than thirty-six hours up to a temperature of 2,000 degrees, and with intervals of hot and cold, and yet the roof remained sound.

ASPECTS OF APPLIED ÆSTHETICS.—II.

THE second of three lectures at the Royal Institution was delivered by Mr. James Paterson, A.R.S.A., R.W.S., R.S.W., last week. It was entitled "Landscape, Old and New." The following is a condensed account:—

Landscape, or landshape, a word which occurs in practically the same form in all Indo-European languages, is defined in a not yet obsolete dictionary as "a portion of land or territory which the eye can comprehend in a single view, including all the objects it contains," and secondarily, "a picture representing a tract of country with the various objects it contains."

This is surely a very prosaic and unsatisfactory explanation of what is suggested to even the most limited imagination by the word landscape, whether it refers to the outspread book of nature or to its interpretation by means of art. Few indeed are the individuals who do not take some interest and derive some pleasure from contact with what lies outside of themselves in the visible world. To many the pleasure is largely unconscious; but any attempt to analyse the real sources of enjoyment will convince the most unsophisticated the sources are complicated and, in a majority of cases, very different from what is imagined. City dwellers especially, for whom the country is commonly associated with freedom from restraint, change of scene, and absence of worry think, when on a holiday, they are under the spell of æsthetic influences. Opportunities for sport or active exercise, the stimulus of purer air, even, nowadays, the intoxication of more and more rapid locomotion, are by many confused with the enjoyment of nature's beauty. To others the scientific aspects of things are the true sources of pleasure. Or the interest may arise from thoughts quite unconnected with any visual charm the scene may possess. Analogous to this is the uplifting of spirit aroused by outspread country seen from a commanding point of vantage, though even here very many people are mainly gratified by the unusual exercise of their visual powers, and confuse the unexpected and joyful perception of rarely seen and distant objects with the thrill of emotion aroused in the real lover of nature through some of its simpler manifestations.

Is the perception common of the rare beauty of contour of some nameless hill? Are we sensible of the subtle line of an unknown coast? Do we see with any understanding of its grace the branching of fragile stems against a featureless sky, or the interwoven tracery of vanishing cloud forms in the gathering dusk? What of the infinite gradations of tone in nature? Perhaps a still rarer pleasure hides in the semi-veiling of the forms and shapes of things through sudden shadow or departing light, or when a wind from the west seems to set in motion all beneath the sun, so that nothing is still. What of the delight in colours, so various and entrancing? All unconscious of sources of the keenest pleasure in the common features of things about us we leave the book of nature unopened or trouble not to read in it.

To severely practical people the elusiveness of nature's beauty is confusing and even repugnant; they are annoyed if they do not see distinctly everything within the range of vision. The necessary conditions are seldom coincident with the greatest visual beauty. In recent years photography has increased the popular prejudice that clearness of vision is equivalent with beauty. The photographs of the ordinary landscape are full of facts of a kind, but they are not even approximately true, as will be apparent to anyone who compares them critically with the scene represented. There is reason for thinking that the pursuit of photography, though apparently leading multitudes to regard with some attention the superficial appearance of objects out of doors, has had a somewhat deleterious effect upon the real perception of beauty in landscape; moreover, it renders many impatient of the difficulties attendant upon a more intimate study of nature's varied features.

When we realise the strength of the appeal of landscape and its perennial nature, it seems surprising that the step from admiration to representation was not achieved earlier. It was not till the fifteenth century that the art of landscape painting was evolved, its earliest form being probably in map drawing. Among the giants of the Renaissance the new art showed rapid development, and though mainly used by them as a background for figure compositions it gradually won a place of sufficient interest to warrant serious study. In France, the Netherlands and Spain, appeared artists such as Rembrandt, Velasquez and Claude, who showed the deepest sensibility to the power of nature to arouse emotion. As to Great Britain, Richard Wilson, the last of the ancients, Gainsborough, Turner, Constable, Crome, and many other familiar names bring landscape painting almost to our own day.

In the evolution of landscape painting how various have been the developments! Although we cannot tell what may be in store, changes in point of view and execution are as certain to come in the future as they are evident in the past. No living art can stand still. In modern times the art of landscape painting has been revolutionised.

In the beginning, drawings of objects in nature were made simply to give information. Trees and other features were represented by symbols without any reference to real resemblance. Gradually clearer ideas as to the possibilities of depicting facts gained upon draughtsmen, and there dawned a feeling for arrangement and for colour. But generations of artists succeeded one another before an attempt was made to produce a picture dependent for its main interest upon a rendering of the landscape by itself. Figure painters thought less of natural effect than of significance and fine decoration. Landscape proper achieved emancipation in the seventeenth century and in the two hundred years following (especially in the northern countries of Europe) reached a culmination of grandeur, charm, and dignity which can never be surpassed.

The greatest masters have recognised that it is impossible to invent what is not found in Nature or suggested by it. Nature is the storehouse from which the artist must draw his material. The phrase "To hold the mirror up to Nature" is misleading in the last degree. The artist is born to pick and choose and group with science these elements that the results may be beautiful.

Truth in a picture can only be relative. The forms of

Digitized by Google

things are really visible to us only in light and shadow and colour. There is no such thing as outline; what we call an outline is where one tone of colour ends and another begins. The range of coloured light in Nature is far beyond our means of accurate representation. All have seen dazzling sunlit cumulus clouds rising majestically against what appears as a dark blue sky, but the clouds cannot be represented by pure white paint, the highest note in our scale of pigment; they are full of colour, and yellow and red added to our white paint detract from its lightness. The blue sky, again, though dark by contrast with the clouds, is full of light and is far paler in tone than the lightest object in the landscape should the sun not be clearly shining upon it. The landscape itself, however dark it may seem, has infinite gradations in its darkness, and if we try to follow these gradations with our most sombre colours, we reach the lower end of our scale long before the deeper tones in Nature have been indicated.

The darkness of the older pictures of landscape is not entirely due to age. Their authors were concerned with composition, style, dignity of presentation, and strove for decorative effect both in form and colour; the latter, whatever the subject, restrained and restful in schemes of drabs, blues and browns and greens. So accustomed had artists and public alike become to this treatment of the coloured tones of Nature that when, early in the nineteenth century, a new perception of the possibilities in artistic statement of natural phenomena dawned upon Constable, his works were received with derision. Tradition handed down from generation to generation had so blinded people's eyes that these pictures were really not understood, and condemned as lacking in the qualities which they pre-eminently possessed; above all, approximate truth to Nature's lighting.

The brown convention survived almost to our own day. It died hard. The pictures were restful to the eye, pleasantly uniform in aspect, admirably fitted to take their places quietly as articles of furniture in the most refined households. Decorative qualities are essential to all fine art—pictures form no exception; but he who can find no room for such in his scheme unless they are produced under the old limitations as to colour shows a slight misunderstanding of the possibility of helpful environment. There is at present a fashion to banish the picture from the homes of our great middle class. Architect and decorator combine to so cover the walls of the public rooms with panelling and other structural features there is no space for more than a brass plate. Some years ago a man who had fine modern pictures was showing them to a well-known architect, who made the suggestion that for the price of one of his Corots he would transform his drawing-room into as complete a work of art as any of his cherished landscapes. The commission was given, the room was transformed, the result was much admired; but the pictures had to go; they were no part of the scheme and interfered with it. After a year their former owner found he missed his quondam friends, and, visiting the dealer to whom he had sold them, explained his feeling of loneliness in his lovely drawing-room, where, even at the risk of injuring the decoration, he felt he must have his pictures again. Panelling in wood forms a pleasant and durable treatment of wall spaces, but indiscriminately used, and cut up, as it often is, into distractingly small sections, it is not a suitable background for pictures. The result in too many modern rooms gives an impression of anonymity; no opportunity remains for the inmates to show their idiosyncrasies of taste; one might mistake such on entering for the board-rooms of insurance companies or the restaurant of an hotel. The renaissance of the minor arts and crafts within the last twenty years has been phenomenal, and has added a much-needed grace to modern life; but the possessor of pictures, who has acquired them for the satisfaction of his own inclinations, is provided with an element of enjoyment in his home which no bric-à-brac nor other decoration can supply in anything like the same degree.

In conversation with a distinguished architect a landscape painter was advised to dispense with the production of canvases destined for no place in particular, and train himself instead to execute work of a character to fit in with schemes of decoration designed by those in the sister profession. The reply was forcible and to the point:—"What we are trying to do is to make pictures which it will take the best architect all his time to design a good enough wall space for them to hang on." There is much need for the training of thoroughly qualified intelligent artificers to carry out the ideas of the architectural profession, but it would be a fatal day for vital landscape art in England if the free expression of emotion by means of pigment were rendered impossible. Far too many poor pictures are produced; they will disappear in time and be forgotten: but there is always the possibility that a veritable creation may result from an artist's labour. It is this hope which sustains him in his struggle, be the hope never so long deferred.

The difficulties in the modern landscape painter's art have been enormously increased by the modern's desire to express himself in colour bearing some resemblance to those in Nature, and to suggest, if not to indicate, Nature's own light. When a student loses touch with Nature he is in a perilous state. No definite course of life study can be specified. But to paint landscape and find out for oneself its possibilities it is well not to flirt with a new neighbourhood each recurring summer, but to (metaphorically) marry some well-chosen place and live with it spring, summer, autumn and winter, seeking not the obvious picturesque, but allowing Nature's features to find their way to the heart and thence issue in sentient artistic expression.

There is a wide field of subject matter for the landscape painter. By common consent our own land is one of the most richly dowered with beauty, the very fickleness of the climate giving it an added charm. One would expect a painter to feel and render the character of his native country with greater success than that of strange places, but the unexpected is always happening in art, and in this matter no such rule can be laid down, especially in these days of convenient travel. Many landscape painters find a stimulus in the new and unaccustomed aspect of foreign places. It is not in the most awe-inspiring scenes of nature that the great masters have found their material; inaccessible mountains, cataracts foaming from giddy heights, the fury of tempestuous seas, supply motives better suited it would seem to the musician or the poet than to the painter, however deeply he may be moved by them. The wild and uninhabited parts of the earth appear to lack what gives the necessary stimulus. Why this should be is interesting psychologically; perhaps the most potent reason for the almost universal choice of the less grandiose phenomena is that however much the artist may wonder and admire he must not be dominated by nature. He is the master, not the servant. What we ask of him is what he feels and sees expressed in terms of beauty, not a craven chronicle of facts, however sublime in their scientific bearing, however faithful in their archæological correctness. Hence we find the simplest materials seen and interpreted by genius becoming masterpieces which will endure for ever. Chardin so painted some apples and a pewter jug that we receive a new inspiration of what vision may be. In a little Cotman we may see some mean buildings so persuasively rendered in colour and quaint light that the elaborate classical landscape hard by seems paltry in comparison. Whistler, like a great violinist with muted strings, has left us the haunting beauty of summer night. Corot, with a few stunted trees and an apparently featureless horizon, creates a vision of the world at dawning which seems almost to breathe the spirit of the moment. A landscape by Matthew Maas again, the subject so simple as to almost beggar description, the result arresting in its marvellous impression of muffled silence. All these were great painters, all were misunderstood during a great part of their lives, the result of obeying their own instincts, their own individual method of looking at things.

Herein lies the root of the matter; all vital landscape painting exists only and simply as the interpretation of nature by one man, not in response to a public demand, in no way influenced by what the public wants, refusing what is clamorously asked. The world's wishes in these matters are met in the travesty of all the arts, the temptation to give what is wanted comes with no veiled appeal, and we need not look far for examples of men nearly great succumbing to it. A man must live, they say to themselves; wife and children have the first claim; nobody cares for what we delight in; we shall give them what they want.

There is nothing entirely new in this experience. Innovators have always been forced to wait for understanding and recognition in all departments of human activity till they have educated a public sufficiently large to make a livelihood possible. The tragedy is too often repeated of the public learning its lesson when the despised innovator can no longer benefit by its appreciation, having sunk into his grave soured and embittered by frustrated hopes of recognition. The ingrained conservatism of mankind exacts this toll, and from its most gifted sons, and treating them much as the Jews treated their prophets of old, persecutes or rather neglects them in their lives, and builds monuments to their memory.

We are apt to imagine that such things happened long ago, but are impossible in this enlightened age. Within the

Digitized by Google

last few years there have been examples to the contrary, and it is certain that at the present moment many such lie not beyond our reach.

Whistler denied that there ever was an artistic period in the history of the world; at no time, he states, was there an art-loving nation. More's the pity! But in the far off fruition of all things, surely beauty will come to its own!

Meantime we hold the field, and play our part more or less well or ill, as the case may be, by ourselves and with our generation. We were never intended to succeed in anything, said R. L. Stevenson, only meant to keep on trying. Let us give ourselves a chance then in the finer things that last. The younger people should cultivate a feeling for simple things, and not be afraid to be original in the quest of enjoyment. Forget, perhaps, the task-work learned at school, but sometimes, at least in country walks, let nature appeal to the heart as a whole. Never mind for a day what is the scientific name for the rock which forms a range of cliff, but see how sheer and sweet it is between the sun and the sea. Do not trouble to remember whether those filmy clouds are cirrus or cumulus, but rejoice in the grace of them and marvel at their vanishing. Should all nature be in a whirl of movement, spare complaints of the wind and the rain and sing in tune. Or again, if you have hitherto failed to take any definite interest in pictures apart from their subject, go to an exhibition some morning when it is not crowded, and, without consulting the catalogue, walk quietly round till you come to something which seems strange to you. Consider it receptively, first from a distance, then nearer if you like. Do not try to find fault, nor be in too great a hurry to audibly admire. Most likely many weeks' or months' work went to the designing and making of it. Give it time to penetrate with its message.

The result will most likely be surprising.

ESSENTIAL FORMULÆ IN STRUCTURAL ENGINEERING.*

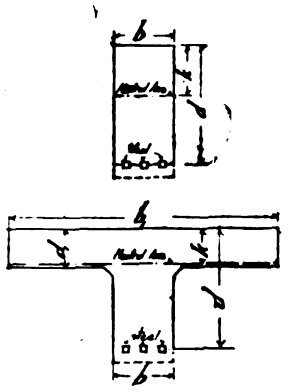
(Concluded from last week.)

THE finding of the position of the neutral axis is probably the most difficult of the several operations necessary in the calculation of a reinforced concrete beam, and in ordinary calculations the position arrived at is only hypothetical, for the neutral axis in such beams varies in position according to the extent of the loading of the beam and the consequent variations in the moduli of elasticity of both materials. The old beam theory that sections remain plane sections both before and after bending is generally accepted for the purpose of practical calculations for reinforced concrete beams. Many authorities, indeed, question its exact theoretical applicability to such beams, but almost all admit that the results of calculations on such basis are sufficiently near for practical purposes. The position of the neutral axis varies in accordance with the ratio of the area of steel to the area of the concrete, and also in accordance with the ratio of the moduli of elasticity of the two materials. In practice, however, the ratio between the two moduli being taken as constant the position of the neutral axis in any particular beam of fixed sectional area varies only in accordance with the ratio of the area of the steel to the area of the concrete, or to, as it is more often termed, the percentage of reinforcement, any increase in the area of the steel causing the neutral axis to become closer to the steel.

The calculations for finding the position of the neutral axis are so involved that a formula becomes an almost essential aid. But recourse to calculations for finding the neutral axis will rarely be necessary in the case of beams not connected to slabs, for the values of k for varying percentages of reinforcement are given in the report of the R.I.B.A. Reinforced Concrete Committee and in most reinforced concrete text-books, k being the proportion of the depth (measured from the top) at which the neutral axis is situated.

The values of k given in the R.I.B.A. report for a few ordinary percentages are:—

0.7	per cent. or	.007	ratio of steel to concrete		.365
1.0	,, ,,	.010	,, ,,	,,	.417
1.5	,, ,,	.015	,, ,,	,,	.483
2.0	,, ,,	.020	,, ,,	,,	.530



When, however, a T-beam, in which the floor slab assists the ordinary rectangular beam, is dealt with, the depth of the neutral axis does not vary in any fixed proportion with the amount of reinforcement. The use of a formula in this case is therefore necessary, and as the formulæ applicable to T-beams are derived in a similar manner to that applying to ordinary rectangular beams, all three are given.

* A paper presented at the general meeting of the Institution of Municipal Engineers, held at the Building Exhibition, Olympia, April 24.

Essential Formulæ (3).

rectangular beam $k = \sqrt{(p^2 m^2 + 2pm)} - pm$

T-beams $k = \sqrt{\frac{2A_t m}{b_1 d} + \frac{A_t^2 m^2}{b_1^2 d^2}} - \frac{A_t m}{b_1 d}$

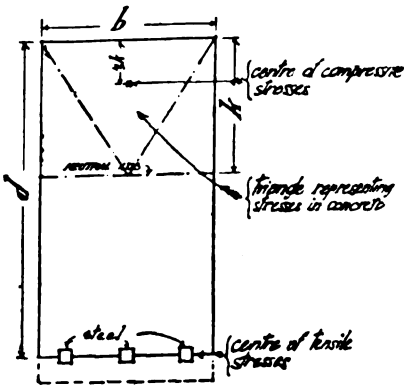
T-beams where the neutral axis comes *below* the slab.

$$kd = \frac{b_1 d_1^2 + 2A_t md}{2b_1 d_1 + 2A_t m}$$

the distance previously $\frac{1}{3}\,kd$ equalling $\frac{d_1}{3} \times \frac{3kd - 2d_1}{2kd - d_1}$

when (the above being the R.I.B.A. Committee's symbols)—

k = the proportion of the depth of the beam (measured from the top) at which the neutral axis is situated.



b = breadth of beam
b_1 = breadth of the portion considered as the table of the T
d = total depth of beam
d_1 = depth of slab
A_t = area of steel in tension

} The same units of length and area being respectively used throughout.

$p = \frac{A_t}{bd}$ = ratio of section of metal to section of concrete (often termed the percentage of reinforcement)

$m = \frac{E_s}{E_c}$ = ratio of moduli of elasticity of steel (in tension) and concrete (in compression)—usually 15.

The position of the neutral axis having been ascertained, it will be well to note the position of the centres of the tensile and compressive stresses in the beam. As regards the steel, the centre of the tensile stresses will obviously coincide with the centre of gravity of the metal. As regards the concrete, the stresses, as in the case of all rectangular beams, vary from zero at the neutral axis to maximum at the outermost layer, and may be represented in the form of a triangle, and the centre of such compressive stresses is situated at the centre of gravity of this imaginary triangle, which is to say, one-third the height of the triangle or one-third k.

Coming now to the method of calculating the strength of beams of reinforced concrete, in ordinary cases it will be found that the beams are not merely supported beams, but that they are to some extent either fixed at the ends or continuous over supports, and in practice where loads are dis-

Digitized by Google

tributed it is a general custom to allow for a bending moment of $\frac{WL}{12}$ at the centre and $\frac{WL}{24}$ at the supports. In the case of slabs the bending moment will be $\frac{WL}{12}$ if the slab is reinforced in only one direction and $\frac{WL}{16}$ if reinforced in both directions.

The R.I.B.A. Reinforced Concrete Committee give the following formulæ for working out rectangular beams:—

$M = A_t t (d - \frac{1}{3} kd)$, which is the moment of resistance of the steel, and $M = \frac{1}{2} A_c c (d - \frac{1}{3} kd)$, which is the moment of resistance of the concrete.

When A_t = area of steel in tension, A_c = area of concrete in compression, M = bending moment, t = unit tensile stress in the steel, c = unit compressive stress in the concrete, the same units of force, length and area being taken throughout.

But the use of special formulæ here is not essential, although when the subject is thoroughly understood it greatly conduces to ease and quickness of working. Until a thorough understanding is reached it is well to work on more general lines. It is the old case of the moment of resistance having to be equal to the bending moment. And this moment of resistance in the case of the steel is simply the area of the steel multiplied by the distance between the centres of the tensile and compressive stresses (which result gives in effect the section modulus of the beam as regards the steel), and multiplied again by the safe unit stress of the steel. In the case of the concrete the *moment* of resistance is the area of so much of the concrete as is on the other side of the neutral axis, multiplied by the distance between the centres of the tensile and compressive stresses (which result gives a figure equal to twice the section modulus of the beam as regards the concrete), and multiplied again by one-half the safe unit stress of the concrete. The reason why one-half the safe unit stress has to be taken in the case of the concrete is that, as previously stated, the stresses in the concrete vary from zero at the neutral axis to the maximum at the outermost layer, whereas those in the steel are practically uniform, and in considering the resistance of the concrete the mean stress on the whole of the concrete above the neutral axis has been considered. But if this mean stress on the concrete is allowed to reach the safe unit stress, the extreme stress at the outermost layer, which is exactly double the mean stress, will consequently be double the safe stress of the material, which, of course, must on no account be allowed.

To persons so well conversant with mathematics and with the theory of this special subject as to be able to think in formulæ, all this rather lengthy treatment of the elements reinforced concrete beam design may appear useless and unnecessary. But I believe that there are not a few persons —I unblushingly number myself with them—who prefer to talk and think of a spade as a spade without wrapping it up in some disguise of x and y. A formula undoubtedly constitutes a most valuable form of expression—when you understand what it means, but not until then. And I believe a lack of appreciation of the true meaning of reinforced concrete formulæ is responsible for that unfortunate kind of half belief that in the case of this material some special principles of mechanics apply. The most lucid explanation in Gaelic is hardly likely to convince a Londoner, nor will the most beautiful exposition based entirely on symbols be of much value to the man who is of a practical rather than a mathematical turn of mind.

In addition to the compression and tension in beams of any material, there is also the shear to be considered. This can easily be obtained without formulæ, the shear at the supports being equal to the reactions, and the shear at any other point being equal to the amount of the nearest reaction minus any load or loads between such point and this reaction. Reinforced concrete beams have been found to fail by what is termed diagonal tension due to shear. The amount of the diagonal tension at any point may be ascertained by finding the resultant of the vertical and the horizontal shear. These shearing stresses, of course, being equal to one another, the resultant is at an angle of 45° with the direction of either of them, and amounts to the stress multiplied by $\sqrt{2}$.

In practice, to obtain the amount of the diagonal tension to be taken up by the steel, it is necessary to consider only so much of the shearing stress as is in excess of the safe resistance of the concrete to vertical shear.

Allusion has on several occasions been made to allowable safe stresses. These in the case of a few everyday materials are generally accepted as being about in accordance with those given in the following table:—

—	Tension.	Compression.	Shear.
	Per square inch.	Per square inch.	Per square inch. With grain.	Across grain.
	lb.	lb.	lb.	lb.
Timber (deal) ...	800*	800*	40	250
„ (oak) ...	900*	1,000*	100	600
Concrete of the very best quality, mixed in the proportions of 1 Portland cement, 2 sand and 4 of aggregate ...	50 tons.	500* tons.	at least 60 tons.	
Cast iron ...	1½	8	2	
Wrought iron ...	5	4	4	
Steel	7 (7½ tons is often taken).	7	5	

In dealing with this question of beams, semi-beams or cantilevers are intended to be included, and it should be remembered that beams are not only horizontal, but very often vertical. There are particularly several kinds of vertical cantilevers met with in ordinary construction. Among these are walls retaining either earth or water, although sometimes such walls are held both at the top and bottom, and thus become beams. High chimney shafts and high enclosure walls subject to wind pressure are other examples of vertical cantilevers.

The methods of obtaining the overturning or bending moment, in the case of structures subject either to wind or water pressure, are in no way in dispute. In either case it is the external forces acting at the centre of application multiplied by the distance of such centre of application from the base of the wall. In the case of wind pressure, this centre will be at the centre of gravity of the area acted upon by the wind. In the case of water, where the pressure varies from zero at the top to maximum at the bottom, and may be graphically illustrated in the form of the triangle, the centre of pressure is at one-third the height of such triangle.

When, however, earth is dealt with, there are numerous formulæ, none of which appear to meet with absolute acceptance, but Rankine's formula is undoubtedly the most well recognised.

***Essential Formulæ* (4).**

For a bank with a flat top $P = \frac{wh^2}{2} \times \frac{1-\sin\phi}{1+\sin\phi}$

For a bank with a sloping top $P = \frac{wh^2}{2} \times \cos\theta \frac{\cos\theta - \sqrt{\cos^2\theta - \cos^2\phi}}{\cos\theta + \sqrt{\cos^2\theta - \cos^2\phi}}$

when P = the total pressure of earth acting parallel to the surface at a point situated at one-third the height of the wall; w = weight; h = height; φ = angle of repose of earth; θ = angle of slope of top of bank. The same units of force, length and area applying respectively throughout.

It is clear that without some symbolic representation Rankine's method of obtaining the pressure of retained earth would be most difficult both to remember and to apply. The amount of the earth pressure having been obtained, the wall can be worked out as a vertical cantilever. Where the wall has a flat top it is also possible to obtain a satisfactory solution of the problem by means of graphics.

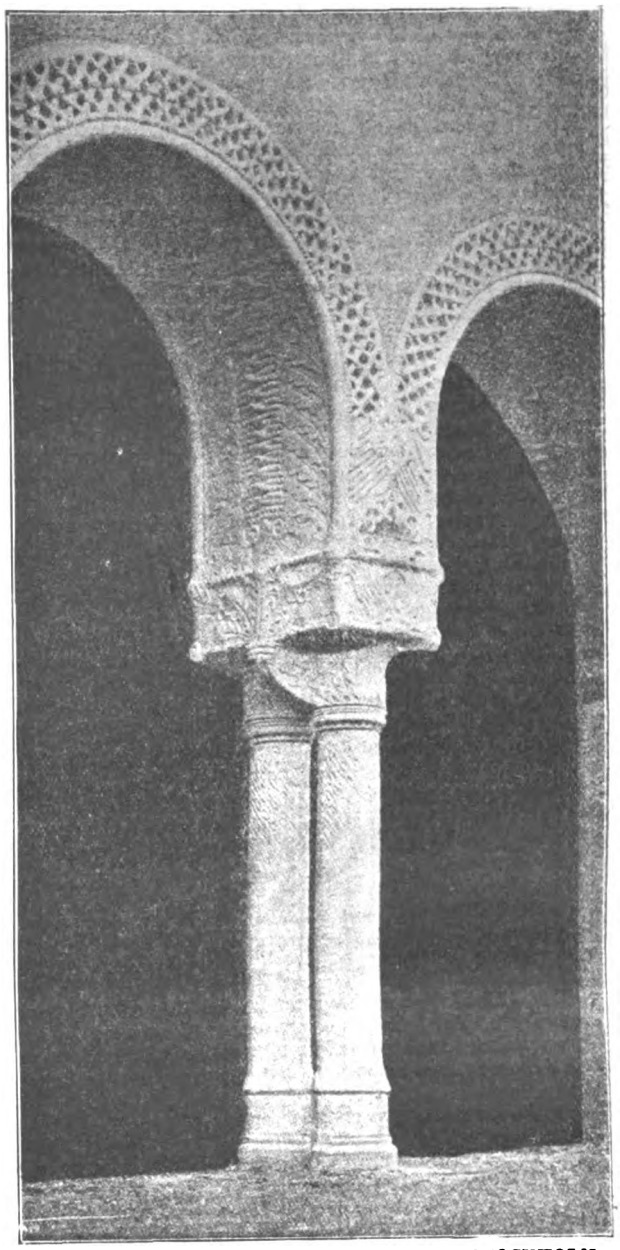
When the resistance of the wall to the pressure is being considered the question arises whether any tension on the joints is to be allowed. In theory, tension is considered undesirable, but in practice a small amount of tension is often allowed. The moment of resistance of the wall having been ascertained just in the same manner as that of an ordinary rectangular beam, if no tension whatever is to be allowed the unit tensile stress found by equating the moment of resistance to the bending moment must be neutralised by, and must consequently never exceed, the unit compressive stress due to the weight of the wall. If it is decided to

* These are stresses in direct compression and tension. The allowable "beam stresses" in both compression and tension are 1,200 lb. in the case of deal, 1,500 lb. in the case of oak, and, in comparison only, 600 lb. in the case of concrete.

Digitized by Google

allow tension, the amount by which the intensity of the tensile stress exceeds the intensity of the compressive stress should not be more than the safe tensile resistance of the material forming the joints. Where a graphic solution of the problem is attempted, in this case, as is well known, there will be no tension in the joints if the resultant formed by the composition of the forces due to the pressure and to the weight of the wall does not fall outside the middle third of the base.

High chimney shafts, whose stability can be calculated in an exactly similar manner, with the difference that the overturning moment is more easily ascertained, are almost invariably designed on the basis of there being no tension on the windward side, a policy with which few engineers will disagree, although many may question the necessity of allowing for such high wind pressures as 40 lb. to 50 lb. per square foot on the narrow surface offered to the wind by an ordinary chimney shaft.



BEAM STANCHIONS.

Cases not infrequently occur in practice where a member acts as a tension or compression member, and also as a beam or cantilever subjected to cross-strain. A steel tie beam of a roof, carrying a ceiling suspended at intervals throughout the "span" of the tie beam, is an instance of tension combined with cross-strain being produced. Stanchions forming part of a retaining wall, and also bearing a load, and principal rafters carrying purlins at points intermediate between the struts, are instances frequent in occurrence in which allowance has to be made both for compression and cross-strain. The logical method of obtaining the maximum stress on such members is to add to the tensile or compressive stress, due either to direct pull or load the additional tensile or compressive stress due to the cross-strain. The total tensile or total compressive stress, as the case may be, is thus obtained. In the case of members subjected in the first instance to direct tension, the total tension may, of course, be allowed to reach the safe tensile stress of the material. Dealing, however, with compression members subject also to cross-strain, the greatest stress which may be allowed is a much more variable quantity. Consider, for instance, the case of a steel stanchion stressed in this manner. Treating the member as a beam only, a stress of at least 7 tons is allowable, but considered as a stanchion, the allowable stress will be based on the ratio of length to least radius of gyration, and in practice will often be about $2\frac{1}{2}$ to 3 tons per square inch. An absolutely safe course would be to design the member so that the safe compressive "stanchion stress" should not be exceeded, but in most cases this would produce heavy and extravagant construction. The case is one for the exercise of some little judgment. Where the stresses due to the direct load are very much greater than those due to the member acting as a beam, it will not be well to exceed the safe stress calculated on the stanchion basis. But where almost the whole of the stresses are due to beam action, a safe stress approximating 7 tons may be allowed.

The above cases of beam stanchions are in effect exactly similar to that of a stanchion bearing an eccentric load. Here, as before, the compressive stresses due to the load, considered as central for the purpose of this part of the calculation, and to the bending tendency occasioned by the actual eccentricity of the load, should be added together, and should not be allowed to exceed the safe stress of the material based upon the ratio of the length of the stanchion to its least radius of gyration.

Probably it may be said that while proposing to treat of "essential formulæ" I have often strayed some little outside the narrow course to which I might appear committed by the choice of such a title. But a paper rigidly confined to the postulation of a half dozen formulæ would be but a barren enterprise, although in the hands of a capable enthusiast in this direction it might offer an excellent opportunity for a display of mathematical gymnastics, to the great edification of the author and the awe of the average audience. I have rather attempted to deal with the subject from a practical standpoint, giving formulæ where such are necessary, but not otherwise, and also including a reference to the safe stresses on a few common building materials, in order that my paper may not merely constitute a tilt against the serried ranks of redundant formulæ, but may also contain some information of general value.

Mr. J. S. Gibson has taken into partnership Mr. F. P. Skipwith and Mr. W. S. A. Gordon, and their business will be carried on under the name of Messrs. J. S. Gibson, Skipwith & Gordon, architects, 5 Old Bond Street, W.

DETAIL IN THE EXHIBITION BUILDING, STOCKHOLM.
FERDINAND BOBERG, Architect.
(From *Byggnadstidnungen.*)

OUR CONTEMPORARIES FROM OVER-SEAS.

THE *Berliner Architekturwelt* is chiefly occupied with illustrations of the new club-house of the Berliner Lehrervereins, which occupies a site extending from the Alexanderstrasse to the Kurzestrasse. This building is an out-and-out specimen of "new art" design, in which dignity of line is overborne by fussiness of detail. Being "new art," one must not censure the character of the detail, but there is a great deal too much of it.

La Construction Moderne gives three large scale photographs of detail from the ill-fated cathedral at Messina, the examples being the great portal and a window of late fifteenth-century date.

Byggnadstidnungen has some interesting illustrations of details of the buildings in which is to be held this year at Stockholm an exhibition of Swedish industrial arts and crafts, a specimen of which we reproduce. We also give from the same source an illustration of a new church at Arvika. These two examples show how modern Swedish architects are producing excellent artistic work based on their old national art, but without slavish copyism.

The American Architect illustrates the fifteenth annual exhibition of the T-Square Club of Philadelphia, which gives us an opportunity of seeing the sort of work which is there being done in domestic architecture. Some of Messrs. Bliss & Faville's contributions to the new San Francisco are illustrated—namely, the Hôtel St. Francis and the Columbia Theatre.

Digitized by Google

The Engineering Record (New York) contains a quite useful *résumé* of the various methods of employing stirrups in reinforced concrete beams, with criticism of the advantages of different types. A remarkable piece of underpinning of a building eight storeys high in Broadway, New York, is described and illustrated. As the building underpinned has concrete foundations carried down to 25 feet below the street level and supported on piling, the underpinning was somewhat difficult, to protect it from injury by its new neighbour, a twenty-two storey steel-frame building, whose foundations are to be carried down 50 feet or more to the gneiss rock. The problem was not rendered easier by the fact that the soil under these buildings is fine quicksand.

LAW REPORTS.

AT the West London Police Court, before Mr. Garrett, magistrate, on April 28, the case of S. F. Clarkson *v.* Larter (Sections 70 (1) (*c*) and 145 of London Building Act, 1894) was heard.

The defendant had put up, without notice to the district surveyor, a partition dividing a large room on the second floor at No. 14 Norland Square.

Mr. Pierron, who appeared for the district surveyor, argued *inter alia* that as Section 70 (1) (*c*) of the London Building Act might be contravened the district surveyor ought to have received notice, and that the case was frequently occurring.

Mr. G. F. Darker, who defended, stated that there was actually no contravention of the Act, and that accordingly there was nothing for the district surveyor to supervise.

The magistrate decided that notice should have been given to the district surveyor under Section 145 of the London Building Act, 1894, and fined the defendant 1*l.* with costs.

Correspondence

[The Editor will not be responsible for the opinions expressed by Correspondents.]

St. James's Park Proposed Alteration.

SIR,—Now that we have a plan of this scheme, accompanied with Mr. Speaight's own observations upon it, which are published in the current number of the R.I.B.A. *Journal*, a few observations by way of criticism may not be uncalled for.

St. James's Park, as it at present exists, together with the Horse Guards Parade, are expressive of a Royal demesne with pleasure grounds, an open space once devoted to tilting and other sports, and the quarters for the Royal bodyguard, all as adjuncts of St. James's Palace itself, the whole layout and disposition of the parts being just what it always has been in the past. How inappropriate, then, must Mr. Speaight's scheme of revolution appear which entirely disregards these circumstances! And how incongruous must be the result of imposing rigid symmetry where there is next to nothing to suggest it. Had Buckingham Palace been placed axially with the Horse Guards, then there might have been some meaning in a symmetrical treatment; but such is not the case, and the consequence of designing a scheme on uncompromising lines, however ingenious in itself, is here quite out of place, amounting as it does to a denial of all historical and architectural meaning. St. James's Park has many beauties of a natural order, and little, if anything, can be done in this instance by architectural treatment by way of improvement.—Yours, &c.,

R. W. COLLIER.

Designing a Steel Box Girder.

SIR,—In the last issue of your weekly, I notice there is an article by Mr. Henry Adams on the designing of a steel box girder, the theory of which is most lucidly explained. However, the type of beam he has been theorising upon is one which, so far as I know, is impossible of execution; the point I refer to is, how can the four angle irons in the box of the girder be rivetted both to webs and flanges? It would be possible to rivet two of the angles on a vertical axis to both flange and web, and the remaining two either to web or flange; this would leave a girder unsymmetrical, and of unequal strength at any section.

It seems strange that this point should not have been noticed by any of the engineers to whom the lecture was delivered.—Yours faithfully,

J. MYRTLE SMITH, A.R.I.B.A.

Conference on Taxation of Land Values.

SIR,—The Land Tax proposals contained in the Budget will, if adopted, most seriously affect a class of property-owners who already bear more than their fair share of imperial and local burdens. It is therefore incumbent upon all who are interested in land to make their opinions known without delay, and I beg you to allow me to inform your readers that the British Constitution Association has decided to convene a conference of representatives of organisations connected with land to consider the Land Tax proposals of the Budget.

The Conference will be held at the Whitehall Rooms on Friday, May 14, under the presidency of Lord Balfour of Burleigh. Professional, trade, or other organisations connected with land may obtain full particulars on application to the Honorary Secretary, 23 Charing Cross.—I am, &c.,

MARK H. JUDGE.
Chairman of Committee.

British Constitution Association: May 5, 1909.

GENERAL.

Two Hundred and Fifty-five Masons and Workmen are engaged on the new Liverpool Cathedral, the building of which is proceeding without any delay. A height of 65 feet, it was reported to the building committee on Monday, has been reached with the lady chapel, and an average height of 33 feet on the choir. A large portion of the roof in the lady chapel has been completed. The committee also considered and approved the designs for different items of furniture, including the organ for the lady chapel, which will be the first part of the new cathedral to be completed.

Among the Wills proved last week are:—Mr. Edward Augustus Lyle Ould, F.R.I.B.A., of Richmond House, Chester, of the firm of Messrs. Grayson & Ould, architects, of James Street, Liverpool, 24,038*l.* gross, the net being 23,733*l.* Mr. Alfred Henry Paget, F.R.I.B.A., of 1 West Walk, Leicester, architect, who died March 14 last, aged sixty-one years, left estate of the gross value of 19,873*l.* 2*s.* 9*d.*

The Sum Required to secure Lord Leighton's picture "The Death of Brunelleschi" for the permanent collection preserved in Leighton House for the public is 250*l.* Donations amounting to 208*l.* have already been given. A special effort is to be made to complete the purchase this month.

The Bristol Society of Architects held their annual general meeting last week at the Fine Arts Academy. The election of Council and officers for the ensuing year included the following appointments:—President, Mr. Mowbray Green, F.R.I.B.A. (Bath); vice-presidents, Mr. H. Dare Bryan, F.R.I.B.A., and Mr. G. H. Oatley: members of Council, Messrs. G. C. Awdry, F.R.I.B.A., W. L. Bernard, F.R.I.B.A., R. C. James, F.R.I.B.A., W. S. Skinner, F.R.I.B.A., F. W. Wills, F.R.I.B.A., and J. Foster Wood, A.R.I.B.A.; associate members of Council, Messrs. C. F. Dening and G. C. Lawrence, A.R.I.B.A.; honorary secretary and treasurer, Mr. T. H. Weston, F.R.I.B.A.

The Lord Provost's Committee of Edinburgh Town Council recommend the provision of workshops for craft classes at the Edinburgh College of Art on ground available to the west of the existing building. The estimated cost is 3,000*l.*

In Connection with the Royal Commission on Ancient Monuments in Scotland, Dundee finance committee has remitted to the town clerk to call in, if so advised, expert opinion, and to make the necessary report.

The Sheffield Society of Architects and Surveyors held their annual general meeting in the general lecture-room at the University last week, the president, Mr. W. C. Fenton, in the chair. The accounts and annual report of the Council were received and adopted. The ballot for officers resulted as follows:—President, Mr. W. J. Hale; vice-president, Mr. J. B. Mitchell Withers; treasurer, Mr. F. Fowler; hon. secretary, Mr. J. R. Wigfull; Council, Messrs. H. Coverdale, C. B. Flockton, H. L. Paterson, A. E. Turnell, A. F. Watson, E. Winder, W. G. Buck, C. F. Innocent, and H. I. Potter. The past-presidents are also members of the Council.

Mr. Mark H. Judge and Mr. Max Judge, in consequence of the death of their partner, Mr. Leonard Judge, have taken into partnership Mr. Guy Wilfrid Hayler, and the firm will be conducted under the title of Mark H. Judge, Son & Hayler, architects, sanitary surveyors and engineers.

THE WEEK.

THE report given by us on another page of the discussion by the Berks County Council of the objection by the Council of the Royal Institute to the terms of the competition for new county offices at Reading, is typical of the difficulties with which the Institute has to contend, and of the reception that is accorded to its protests against the unsatisfactory conditions that are still, all too frequently, found in the particulars issued by promoters. It is clear that strict loyalty by members to the decisions of the Council and competitions committee of the Institute will alone furnish a sufficiently big stick to prove an argument that will be respected by promoters of competitions. On the other hand, the Council cannot expect that loyalty without greater promptness in dealing with competitions than they have hitherto frequently shown.

WE understand that the circular-letter from some members of the present Council of the Royal Institute sent out with the voting papers was not only unauthorised by the Council as a body, but was inserted without the knowledge of some other members of the Council. Surely this is a very strange proceeding. We do not know whether the signatories of the circular are paying for the printing. If not, the auditors ought to surcharge them with the cost, as it is clearly contrary to the by-laws that any section of the Council, however high their position, can expend the moneys of the Institute without the authority of the Council. If the signatories are paying for the cost of the circular, what right have a few members of the Council to use the staff of the Institute and to take advantage of the expenditure of the Institute to send out their private communications?

THE thousands of architects who are in favour of registration should take note that the signatories of the circular do not intend that a Bill should be promoted in Parliament till all architects have joined the Institute. Presumably this is the policy of other members of the present Council who are opposed to registration—the signatories of the circular appear to imply that they speak for others as well as themselves—and it therefore behoves all members of the Institute who are in favour of registration to elect to the Council those candidates who are pledged to support registration.

WE understand that the following candidates for membership of the Council of the Royal Institute are prepared to support registration:—As *Vice-Presidents*: A. W. S. CROSS, J. S. GIBSON, S. P. PICK; as *Fellows*: A. W. BREWILL, MAX CLARKE, F. R. FARROW, W. A. FORSYTH, ALEXANDER GRAHAM, G. HUBBARD, A. R. JEMMETT, H. V. LANCHESTER, R. F. MACDONALD, C. E. MALLOWS, P. OGDEN, C. H. B. QUENNELL, H. R. RICARDO, E. R. ROBSON, L. SOLOMON, P. B. TUBBS, W. G. WILSON, E. WIMPERIS; as *Associates*: K. GAMMELL, A. E. MUNBY, H. W. WILLS, A. N. WILSON.

ALTHOUGH the Government has expressed its readiness to provide 10,000*l.* towards the sum required to purchase for the nation HOLBEIN'S "Duchess of Milan," we must say that we sympathise with those of our modern painters who feel that far too much importance is attached to the value of "old masters," and that the inflated prices engineered by the dealers are rather due to the rarity than to the excellence of the paintings that fetch such enormous sums. Why should the nation give the present holders of this particular picture 10,000*l.*? For that is what the whole transaction amounts to. There are millionaires in America who would cheerfully give half a million dollars for a picture if they could be persuaded that such is the market value, but who otherwise would not give five hundred for the same work, no matter if it were the finest production of HOLBEIN, TITIAN, or any other "old master." It is the obvious policy of the dealers to work up fictitious values for antiques of every kind—pictures or anything else—and they know very well that, no matter what prices they give at auction in London or Paris, they can find a Chicago pork-butcher or a "King" of some market or other to take up their bargains with a goodly added margin of profit. Sir CHARLES HOLROYD'S valuation of the picture in question is the key of the whole matter. He says "the work was an unique specimen of HOLBEIN'S noble art." Precisely; its market price is the result of its being "unique," not of its "noble art." If there were a couple of hundred more of HOLBEIN'S paintings equally good the whole lot might be bought for a tenth of the price asked for the "Duchess of Milan." There is another point of view. The 10,000*l.* offered by the Government and the 62,000*l.* to be added to it by the British public could be far more advantageously expended in the cause of British Art than by the purchase of a single picture, even though it be "unique."

MR. EDWIN T. HALL, V.P.R.I.B.A., has done good service by promptly pointing out how the Budget proposals of the present year will cripple the great educational institution of Dulwich College, of which he is chairman of the Estates Governors. The charity, it appears, possesses 480 acres of uncovered land, the net income from which is 1,900*l.* Under the Budget Bill this would be charged with a land tax of 1,000*l.*, and this charge would reduce the net income of the whole estate available for education by 7 per cent. Educational and other charities throughout the country would in many instances be, like Dulwich College, sufferers from the proposed taxation of ground values.

THOSE English competitors who have taken part in the competition for buildings in Italy suitable for resisting seismic movements will be interested to learn that the jury has been appointed and has elected as its president Professor ANGELO BATTELLI, of Pisa; vice-presidents, Professor GUIDO GUIDI, of Turin, and engineer LUIGI MAZZOCCHI, of Milan; secretary, engineer C. PINCIROLI, of Milan; vice-secretary, engineer C. CHIODI, of Milan. The jury is to be divided into sub-committees, who will report to a full meeting of the members.

THE Cornwall County Council are making themselves ridiculous. They purchased a site in Truro for new county offices, promoted a competition amongst architects for designs for the new buildings in which fifty-nine sets of plans were submitted, and Messrs. SILCOCK & REAY'S design was accepted, and now there is an opposition on the part of some members of the Council, who do not want the county offices in Truro at all. There is no question that new offices are absolutely necessary, and the matter has been under consideration by the County Council since November 1907. Now the Council has decided to defer the question for three months, when the opposition will propose that the county offices be at St. Austell and not at Truro. The competition for the new offices was not very inviting, as it was clear that the Council did not know how much they would have to spend to obtain the accommodation for which they asked, and there was very little prospect that the scheme for which architects were to prepare designs would be carried out in its entirety. It is very hard that the successful competitors should be placed in such an unhappy position, and we think that the Institute has still one more reform to press forward in open competitions—that they are *bonâ fide*. It is time public bodies learnt that architects do not compete for the premiums, but for the work.

IT would scarcely seem that the case of HANRAHAN *v.* Leigh-on-Sea Urban District Council was of sufficient importance for an unsuccessful appeal to the Divisional Court from the decision of the judge of the Southend County Court to be carried to the Court of Appeal. The result of this further appeal is that the Lord Chief Justice, Lord Justice FLETCHER MOULTON, and Lord Justice FARWELL have decided that the Urban District Council were justified in pulling down an old third-class railway carriage which had been converted into a residence, and hence had become a "new building," and as such did not comply with the local by-laws. Hence one cannot turn old railway carriages into bungalows in districts where the ordinary type of building by-laws operates.

AT ROTHENBURG ON THE TAUBER, BAVARIA.

THE NEW CHARTER AND BY-LAWS OF THE ROYAL INSTITUTE.

THE new Charter, or more properly the Supplemental Charter, 1909, of the Royal Institute has now been printed and issued to the members, together with the proposed revision of the by-laws. The most important provisions of the Supplemental Charter are, first, the creation of a new class of Licentiates; second, the enactment that no person shall "be admitted a Fellow of the Royal Institute unless he shall at the time of admission be either (*a*) an Associate of the Royal Institute or a person who has passed an examination qualifying for admission to the class of Associates, or (*b*) a Licentiate who has passed such examination or examinations as may from time to time be prescribed by the Council as a qualification for the admission of Licentiates to the class of Fellows." So far good; but the Charter goes on:—"Provided, however, that the Council shall have power to elect and admit as a Fellow any architect who shall have attained the age of thirty years, and shall have been engaged as a principal for at least seven successive years in the practice of architecture, as to whom the Council may resolve that it is desirable to elect and admit him as a Fellow." The third provision of some importance is that a certificate of membership "shall be termed a diploma," and the fourth that the Royal Institute may propound a "scheme or curriculum for education in architecture," and in and after the year 1913 no person shall be "entitled to admission to the final examination for Associateship of the Royal Institute unless he shall have passed through a course of study under or in accordance with such scheme or curriculum," as well as have passed examinations.

The words in which provision is made for the creation of the new class of Licentiates are important. The Supplemental Charter says:—"The Council of the Royal Institute shall elect Licentiates of the Royal Institute in manner to be provided by by-laws. Licentiates shall be architects who have attained the age of thirty years, and either (*a*) have been engaged as principals for at least five successive years in the practice of architecture, or (*b*) have been engaged for at least ten successive years in the practice or study of architecture." Licentiates, except by special resolution of the Royal Institute, can only be elected within twelve months after the coming into force of the new by-laws. They are not to be members of the Institute, but may attend and take part in the discussions at meetings of the Institute.

It will be noted that under the terms of the Supplemental Charter Licentiates "shall" and Fellows may be elected by the Council alone. The proposed by-laws enact that the names of all candidates shall be "suspended in the meeting-room and published in the Journal of the Royal Institute," and any objections are to be sent to the Council and considered and determined by them. A further new by-law provides that the election of Fellows by the Council must be unanimous, and that of Licentiates by "an affirmative vote of two-thirds of those present and voting, and in any case of not less than twelve." It is admittedly desirable that there should be some way of admitting to Fellowship of the Institute an architect of high standing, who is at present without the pale, and who could not be expected to submit himself to examination, say, for example, Mr. T. G. Jackson, R.A.; but the power given to the Council might easily be abused, and in view of what has occurred in the past, we may forgive those younger members of the Institute who fear that such abuse is not only possible, but probable. The provision, however, that the decision of the Council in the case of Fellows must be unanimous should allay this fear. It ought to be easy to secure the election on the Council of a number of members who would not hesitate to maintain the principle that the election of Fellows by that body should be the exception, and a very rare exception.

As the avowed object of the creation of a class of Licentiates is to include within the fold of the Royal Institute every person who has the smallest real claim to be considered an architect, there can be little objection to the election of Licentiates by the Council, save that the members of the Council may be disposed to be too lenient and admit those against whom nothing has been said rather than those for whom valid claims have been substantiated. The law of libel and slander in this country is so severe that a member of the Institute might well hesitate before making any statement to the Council, although he might be well acquainted with most damaging facts in the history of a candidate for the class of Licentiates. The Council may, and probably will, say that any such statement is privileged, but there is nothing in the by-laws or in the Charter to this effect, or in any way protecting an informant from the possibility of a libel action.

Professional conduct, ethics, or etiquette, is a subject with which the by-laws deal in an amended fashion. The present By-law 22 becomes now By-law 24, and members and Licentiates are liable to "reprimand" as well as suspension or expulsion. These may now be incurred not only by conduct derogatory to professional character or by engagement in occupations inconsistent with the profession of an architect, but by anyone "who shall refuse or neglect to be bound by a published resolution of the Council." The resolutions of the Council in the matter of professional conduct at present published are, in our opinion, simply puerile, and if the Council can do no better in the future than it has done in the past in this direction, this amendment of the existing by-law should be negatived by the members. At present it is bad form for a member of the Institute to put his name up on a building in course of erection, but all right for him to do so when the building is finished. He must not style himself other than "architect" or "architect and surveyor," and should this by-law be passed as it stands, may be reprimanded, suspended, or expelled if he signs his drawings with R.A. or F.R.I.B.A. after his name.

On the point of professional conduct there are some important additions proposed to the forms of declaration. A Fellow, an Associate, or a Licentiate must sign, "I promise that I will not have any interest in any contract or in any materials supplied to any work on which I may be engaged. I further promise that I will not take part in any competition the conditions of which have been disapproved by the Council."

The first of these promises revives a principle that was maintained by the Institute under the original Charter, but

Digitized by Google

abandoned under the present by-laws. Apart from all other considerations, this vacillation is unworthy of the dignity of the Royal Institute, and must result in the loss of that respect which should be accorded to the premier and presumably representative body of the architectural profession. As regards the proposal itself, there is a good deal to be said both for and against. On abstract principles it is not desirable that an architect should be pecuniarily interested in the supply of material or work for a building with the superintendence of which he is charged. On the other hand, the adoption, again, of the restriction, once abandoned and now proposed to be revived, will no doubt have the same effect as before, and eminent architects will remain outside the Institute by reason of the restriction. Of course, if it be adopted, no member or Licentiate of the Institute can hold shares in any limited company supplying materials of which he has a sufficiently high opinion to include them in his specifications. He must otherwise make his clients take an inferior article because he would have an interest in the superior. Again, it is not an unknown thing for an architect to pick up advantageously old artistic work, panelling, carving and so on. He could not under the proposed by-law sell this to a client who might be eager to purchase. An architect under this restriction could not financially assist a young and talented craftsman by providing him with capital unless he abstained from employing him and gave work to his competitors.

The promise about barred competitions is sound in principle, but if it is to be adopted the Council must treat members more fairly than they do now, and not delay their decision as they have frequently done until half the time allowed for the preparation of drawings has elapsed, or as in the case of the Concert Hall, Eastleigh, until after the drawings were sent in.

An important new by-law is No. 44, which abolishes the present Board of Examiners and transfers its powers to a Board of Education, destroying the independence of the examiners and making them subservient to the Board of Education. The proceedings of the Board of Architectural Education up to the present have not been such as to inspire us with confidence, and their modifications of the curriculum of the examinations are merely high-flown persiflage of which no one seems to know the meaning. The Board of Examiners have at least been definite and comprehensible in their requirements, even if these may be open to criticism by those who, lacking a sense of proportion, attach undue importance to some one aspect of the many-sided problem of architectural education. Not only the Board of Examiners, but the Statutory Board of Examiners is to be abolished, and presumably the candidates for district surveyorships are to be examined under the regulations of the priests of the high-art cult. The amusing part of the *volte face* is that examinations are to be conducted by those who say that one cannot examine in art; hence, if consistency is to be maintained, candidates for membership of the Institute may in the future be utterly ignorant of art.

We are assuming that the constitution of the future "Board of Education" will be substantially that of the present "Board of Architectural Education," and that the new Board will not be the present "Board of Examiners" under a new name.

COMPETITION FOR EXTENSION OF GRIMSBY TOWN HALL.

THE Town Council has now appointed as assessor Sir W. A. GELDER, F.R.I.B.A. The building may extend further on the site than is shown in the sketch-plans, but competitors are advised by the Town Council to take the opposite course and reduce the area built over as far as possible in view of the limit of cost. A design for an entirely new town hall will not be considered.

Members of the Royal Institute of British Architects are requested to communicate with the Secretary before taking part in the above competition.

COMPETITION FOR NEW COUNTY OFFICES AT READING, BERKS.

THE question of the objections of the Council of the Royal Institute to this competition was discussed at the Berkshire County Council on Saturday. The special committee which had been dealing with the proposed new county offices to be erected at Reading reported that a difficulty had arisen with regard to the appointment of Mr. Mervyn Macartney as assessor in connection with the competition. In the conditions of the competition Mr. Macartney was required to report to the Council on the designs submitted and place them in their order of merit, but the Council reserved to itself full liberty to select the design considered best suited to its requirements. The Royal Institute of British Architects, under their rules, insist that the author of the design placed first by the assessor shall be employed to carry out the work, and accordingly they called upon Mr. Macartney to resign his position as assessor, and also forbade members of the Institute to compete unless this stipulation was carried out. The buildings committee now reported that they had reason to believe that the Institute would not object to the County Council having the right to select one of the first three plans placed in order by the assessor, and they recommended that the conditions of the competition be altered accordingly to meet the views of the Royal Institute of British Architects, provided that the County Council was at liberty to select any of the plans placed first, second or third by the assessor, the award or premiums to be left to him.

Sir Robert Mowbray, in moving the adoption of the report, said he was not certain whether the recommendation would meet the views of the Royal Institute, but the committee hoped so. He thought it would be advisable for the Council to authorise the committee as to the line of action they should take if the Institute did not agree.

Mr. Walton inquired as to how the Council would stand if the Royal Institute, as he was afraid would be the case, said their laws were as the laws of the Medes and Persians? He thought it would be as well to suggest an alternative.

Mr. Keyser hoped the Council would not give up its independence in this matter, and that they would have the power of accepting the design which they thought best.

Mr. Wroughton said he did not like the idea of being dictated to by this Institute of Architects, royal or otherwise. They did not contribute to the cost in any way; the Council alone paid the piper, and should have the right to select which plan they thought best. He thought they should throw it open to the profession regardless of the Royal Institute, as it would be a capital opportunity for a young rising architect to send in plans. Personally, said the speaker, he would rather go to France, or even Germany, than be dictated to by this trades union.

Mr. Ferard said he did not think the Council need bother themselves, for there was every reason that the Institute would meet them in the way suggested. They had done so in Manchester and other places.

Mr. Benyon (Lord-Lieutenant of the county) proposed, in the event of the Royal Institute not agreeing with the suggestion, that three or four architects should be asked to submit plans.

Mr. Russell seconded, but hoped that the alternative would not be needed.

Mr. Walton said that they could have an open competition. The majority of architects were members of the Royal Institute, but there were many eminent ones who were not.

Mr. Long suggested that the matter should be left entirely in the hands of the committee supposing the Institute would not agree to their recommendation.

After some further discussion, the committee's report was adopted with the addition proposed by Mr. Long.

The Burslem Town Council have adopted a report of the general purposes committee on the question of utilising the land in Wedgwood Place for public purposes. They recommended that it was desirable and necessary for the purpose of preserving the identity and interests of the town of Burslem that the land should be used for public buildings to be erected at a cost not exceeding 25,000*l*. A sub-committee is to be formed with power to instruct the architect, and obtain plans, estimates and tenders. Before any tender is accepted the committee will report to the Council on the whole question. It is suggested that there should be a hall to accommodate 2,500 people, stipendiary court, children's court, small assembly room, &c.

STEELWORK.—X.

By C. V. Childs, A.M.I.C.E.

In London the designer is met with the difficulty of ascertaining whether his design may have to pass the scrutiny of the municipal authorities. In a building within the meaning of the Act the approval of the steelwork plans is left entirely to the discretion of the district surveyor; in the case of a "special" building, however, the Council demands that the plans, details and the calculations should be submitted to their engineer before their consent be given. There may be occasions where this may be demanded in the case of ordinary buildings, for which application has to be made for permission to depart from some of the regulations.

The two separate, though closely allied, authorities appear to have very different ideas as regards what the strength of the steelwork should be. The Council's engineers are inclined to be over-exacting, and the district surveyors just the reverse in many instances. This is apt to produce an anomalous condition of things in regard to the steelwork for, it may be, different parts of the same building. Of the two the "special" building is more often of less importance than the one governed by the Act. It may often happen that the steelwork has been designed for the main portion of an important building and appears to pass the regulations without a murmur of approval or otherwise. Then an addition, possibly only an open shed over a yard, or something equally unimportant, may be required which comes under the "special" building clause. For this not only the design, but also the details, and perhaps the calculations as well, have to be submitted to the Council's engineers; this design must conform with their requirements, which may exceed by 100 per cent. the basis on which the steelwork for the main and most important part of the building has been calculated.

One hundred per cent. may sound an exaggeration, but in competition steelwork contractors may work to as low a margin as over ten tons per square inch stress for the steel (inaccurately termed a factor of safety of three), and the remaining percentage may easily be accounted for in the reduced amount at which the floor loads have been assumed. Many an architect could bear out the statement that they have had considerable trouble to conform with the Council's structural regulations for buildings such as theatres, &c., but when it came to the question of the steelwork, on which the whole safety of the building depended, no notice whatever has been taken of it except to pass it over to the jurisdiction of the district surveyor. From the draft of the proposed new Building Act the same procedure is to be adopted in the case of the skeleton steel framework.

The district surveyors can hardly be expected to keep a staff of engineers for the purpose of checking steelwork plans; they probably consider that their duties are sufficiently exacting without this work, which has practically become an extra since the Building Act was framed, being also imposed upon them. With all due respect to the Council's engineers, they surely must be aware that the steelwork for all but a very few buildings would fall far short of the standard they require in the case of the "special" buildings. A sample case may be mentioned of how it has been possible within the last three or four years to construct the floors of a building which from its design and position could never have been intended for anything but a warehouse, to which purpose indeed it was put, and that too for a very heavy class of goods. Luckily for the building there were weaker features than even the cross joists, but these will suffice to point the example. The safe load on the cross joists, calculated according to the Council's requirements of seven tons stress per square inch, would have been two-thirds of a hundredweight per square foot. Allowing only three-eighths of a hundredweight for the dead weight of the floor, the difference leaves 33 lb., or but little over a quarter of a hundredweight, as the safe amount of load to be superimposed. Under the proposed new Act it is stated that the superimposed load for a building of the warehouse class should not be less than two hundredweights per square foot; this is almost seven times greater than that in the case mentioned above. This example is enough to show that under the present system it is still possible to erect dangerous structures, and though the district surveyors are the governing authorities in respect to the steelwork, yet their powers of preventing such a state of affairs appear to be limited. Surely a *via media* might be found between the restrictions imposed on a "special" building and the latitude allowed in the case of the more important buildings. To begin with there should be some authority to which the designer could appeal to settle what the amount of the superimposed loads should be for buildings to be used for special purposes; apparently, from the writer's experience, no assistance can be expected in this respect from the district surveyors. The designer would willingly work in conjunction with the authorities if the means were provided to enable him to do so; at present these two are antagonistic to one another, mainly on account of the severity of the restrictions imposed by the Council's engineers when the steelwork comes under their jurisdiction. Surely the way might be made easier and the authorities and the designer brought more into harmony with one another. If it is possible to-day for the steel contractor to design his work at a stress of ten tons per square inch, the authorities might see their way to reduce their minimum of seven tons stress; so, too, as regards the stanchions the safe allowable stress in the proposed new Act is apparently based on what has been called the R.I.B.A. formula, only in a more exacting form. For a stanchion whose length is ninety times its radius of gyration the proposed allowable stress is three and a half tons per square inch. For twenty years the Carnegie Steel Company have worked to a formula that allows five and one-third tons stress for a similar stanchion; according to Messrs. Dorman, Long & Co.'s handbook the safe stress would be 4.6 tons per square inch. The formula adopted by the Council's engineers is probably the most severe of any that has been applied to stanchions for building work. The writer, with all due deference, would suggest that a minimum rather than a maximum standard should be adopted by the authorities and made applicable to steelwork for all buildings, whether within or outside the meaning of the Act; at present it might be inferred that the authorities, by placing the steelwork under the jurisdiction of the district surveyors, are loth to enforce what they consider is requisite when their engineers are the arbiters.

If their requirements were universally enforced it would certainly cause considerable commotion among steelwork contractors; but by imposing reasonable restrictions as to the strength of steelwork for all buildings the contractors would know that in cutting down the steelwork below the required standard they were doing so at their own risk, and they would be liable not only to having their material rejected, but also for damages on account of delay in flagrant cases. If such regulations were framed and carried out in a true spirit of equity the authorities might call upon the architect or the designer to furnish a certificate that the steelwork was designed to conform with certain assumed floor loads and also with the regulation allowable stresses. This would at least put the onus for the safety of the building on to the shoulders of some responsible person, and should be a safeguard against reducing the limit of safety to a vanishing point, even though it could not entirely eliminate so-called errors of judgment.

The specification should be brief and to the point; the longer it is the less attention it will probably receive. A great deal depends on whether the work is to be properly inspected by a firm of inspection engineers. This matter will be referred to later.

It is useless including in the specification clauses that it is impossible to see carried out, and yet the writer invariably does so in one instance, where no inspection is to be made at the rolling mills, in the hope that some day the practice may become universal. This clause reads:—"The contractor is required to produce guaranteed particulars of the tests made at the rolling mills on the melts from which the material used in this contract is rolled; the melt number to be stamped on all material before leaving the mills."

The contractor orders the material from the mills according to his own specification. It is usual for the mills to supply him with particulars of the tests made on specimens of each melt or heat from which his material is rolled; the melt being each separate charge of the furnaces, which when converted into steel is poured into the ingot-moulds, thence passes through the blooming mill and, after being cut to lengths, is rolled to its approximate shape on the breaking-down mills, finally appearing as the finished section after passing through the finishing rolls. The melt number should be stamped on all mill lengths; this serves as an identification mark for all material leaving the mills, so that it can be traced back to its particular melt, the tests on which can be inspected. This, in the writer's opinion, is a better guarantee of good material than that of specifying that certain samples should be provided by the contractor and sent to a testing laboratory, which is a more or less haphazard method for ascertaining the quality of the steel.

If such tests are unsatisfactory, the difficulty then is to determine what is the amount of the material affected by these tests. The test specimens may have been cut from one melt, but the majority of the material may have been rolled

Digitized by Google

from entirely different ones, and there is no means of tracing back the material to its own particular melt.

For a rough-and-ready method of determining the quality of the steel the bending test is in general sufficient for the purpose; it is easy to apply, and can be done at the works without having to send the test pieces to a laboratory if no testing machine is at hand. If the test specimens will stand being bent cold around a rod whose diameter is the same as the thickness of the test piece without showing any appearance of fracture, then the material may be considered of sufficiently good quality for the structural steelwork for buildings. This is a sure test for the ductility of the steel, which after all is its most important factor for girders or beams. Any overloading on such a beam would make itself apparent not by its collapse, but by its excessive deflection, and would automatically notify the state of affairs to any casual observer.

An occasional visit to the shops and the tapping of the rivet heads can hardly be called inspection, and yet it is about all that a consulting engineer is able to do in this respect; such inspection might just as well be deferred until the material is delivered at the site. In America consulting and inspecting work are two distinct and separate branches of the engineering profession. In that country the inspection of the steelwork for any important building is placed in the hands of a firm of inspecting engineers, who have their regular staff of inspectors located at the various mills and within easy reach of the shops. Proper inspection must be thorough. It begins at the rolling mills by making physical tests on the steel from which the various shapes are rolled, which, if passed, are stamped by the inspector before leaving the rolling mills. Inspection at the shops calls for the continual and not the sporadic attention of the inspector. He watches it pass through the various processes of punching, drilling, assembling, rivetting, &c.; he checks the lengths, the open holes and the connections by his copy of the working drawings, and finally checks the weight of each delivery as it leaves the shops. Another important function he performs is to so regulate the timing of the delivery of the material, first from the rolling mills to the shops, and then from the shops to the site, that the material arrives as it is wanted and in its proper sequence. From this it is evident that only a firm with a specially organised staff of inspectors is able to give this work the attention it requires if this work is to be performed in a proper and thorough manner, and unless so done it can hardly be designated inspection.

THE ARCHITECTURAL ASSOCIATION ANNUAL DINNER.

THE annual dinner of the Association was held on Wednesday, May 12, in the Gaiety Restaurant (Georgian Hall). The chairman was Mr. Walter Cave (President). Among those sitting at the head table were Mr. Ernest George, P.R.I.B.A., Sir W. B. Richmond, R.A., W. Howard Seth-Smith, Past President A.A.; E. A. Abbey, R.A., T. G. Jackson, R.A., E. Guy Dawber, Past President A.A.; Solomon J. Solomon, R.A., H. Greville Montgomery, M.P., Sir A. Brumwell Thomas, Vice-President A.A.; A. D. W. Pollock, Master Plumbers' Company; Professor R. Blomfield, A.R.A., G. E. Bond, J.P., President Society of Architects; John Murray, H. C. Cole, President Surveyors' Institution (Junior Meetings); J. A. Marshall, A. Fincham, President Clerk of Works Association; H. T. Buckland, and at the other tables were H. P. G. Maule, Professor E. C. Alston, R. Frank Atkinson, Gerald C. Horsley, W. Curtis Green, Theodore Fyfe, Louis Ambler, William Wallace, F. R. Farrow, G. Gilbert Scott, Maurice E. Webb (Hon. Secretary A.A.), R. Dircks, Neville Cooper, C. W. Bowles, B. de Q. Quincey, Stanley Towse, H. G. Tayler, A. W. Bartlett, A. H. Ryan-Tenison, Ian MacAlister (Secretary R.I.B.A.), F. Winton Newman, A. E. Bullock, W. G. B. Lewis, G. H. Jenkins, Stanley Hamp, Leslie Lambert, Harrison Hill, A. Needham Wilson, Louis Jacob, T. L. Dale, W. Paul, Albert Fox, Ernest Mills, D. G. Driver (Secretary A.A.), C. Luff, Harold Green, T. Frank Green, C. R. Davy, E. Gunn, C. H. Freeman, C. W. Ferrier, H. B. Elkington, G. Leonard Elkington, G. Northover, Professor G. Moira, C. E. Hutchinson, F. R. Betenson, Guy M. Nicholson, G. B. Carvill, S. M. Spoor, M. W. Zambra, C. Wontner Smith (Hon. Sec. A.A.), D. Warry, Chas. Tanner, E. Harding Payne, W. Dewes, A. J. Perrin, Percy May, R. P. Oglesby, Ellis Marsland, F. J. Osborne Smith, Philip E. Webb, A. F. Spencer, G. D. Gordon Hake, F. Yerbury, F. J. Worrow, Walter Lawrance, T. Raffles Davison, W. H. Jamieson, H. Saffery, Herbert Batsford, L. M. Gotch, G. E. Mills, H. C. Willies, F. A. Davis, J. Williams, Arthur Keen, Henry Tanner (Vice-President A.A.).

After Mr. WALTER CAVE, President, had given "The King and the Royal Family," he said that he had to make a slight alteration in the order of the toast list, inasmuch as Mr. T. G. Jackson, R.A., who was to propose "The Architectural Association" had to leave early in order to catch a train. That toast would therefore be given before that of "The Royal Institute of British Architects."

Mr. T. G. JACKSON, R.A., on rising, said he gave the toast of "The Architectural Association" with much pleasure. He felt for them the greatest interest as well as a sincere admiration, because at one time it was the only body which did anything for the education of young architects. It originated in a desire for mutual help. The Association had always put teaching before examination, and had never fallen into the fallacy that education and examinations were the same thing. For that and for other reasons it was entitled to great commendation. It was a fact, remarkable of late, that examinations in general had fallen into disrepute. Some years ago when the Royal College of Arts was being reorganised, the committee (of which he was a member), decided that certificates should be awarded not as the result of examinations—which often had a fictitious value—but rather for general work. The Architectural Association had followed something like that system in their school. The last annual display of work was highly creditable, and he was especially struck by the holiday sketches. It was only by going about and seeing and studying the good work of our predecessors that architects could hope to equal or surpass them. But sketching was not practised as in his young days, when it occupied every Saturday afternoon and autumn holiday. Architects had the proud knowledge that their occupation was not merely for a livelihood, it was also their greatest pleasure. They, as a class, could never look to become very rich, but they were repaid in other ways. Mr. Briton Riviere, R.A., recently told the story of a distinguished artist who in taking his walks abroad came upon a young painter busy on a landscape. After he had duly encouraged him the older man said, "May I ask what you make by painting?" The other replied it was about 150*l.* a year. "Oh! 1150*l.*" The younger man corrected him, it was 150*l.* he had said. This distinguished painter then told him that he always added 1,000*l.* to his receipts, as being equivalent to the pleasure he received out of his work. This was no less applicable to architects. With the toast of the Architectural Association he coupled the name of Mr. Cave, their president.

Mr. WALTER CAVE, in responding, said he had first to thank Mr. Jackson for his kind words, and the honour he had done them in coming to the dinner, and also in sending his son to the Association's school. The schools were going strong; the same number of students as last year attended the day-school and about the same number the evening classes. This was quite satisfactory. On such an evening it was impossible to go into the difficulties of architectural training. But he might point out that at the Association schools they had to provide an education that began at the beginning, and to give it to a very varied class of men. Some came from the public schools and universities with the power of learning fully developed. Others, not blessed with the same advantages, came to them without that power—though full of enthusiasm. The difficulty which faced the Association was how to provide education for students who started with such widely differing powers of acquiring knowledge. Mr. Maule, who played so prominent a part in the school, had been considering that problem. Another question they had in hand was the finding out as soon as possible whether the student was suited for following their profession. It was there that their real responsibility lay. That their elementary teaching was sound was proved by the approval given to it by the profession. Though whether they had been stringent enough in the past in eliminating the unfit was open to question. In the future, things would be stricter. As to himself, he might be pardoned for making one or two remarks. He had acted as President for two years, and, moreover, enjoyed the unique distinction of having presided at three dinners. During his term of office the building debt had been extinguished, and nearly 12,000*l.* paid off—chiefly through the help of other members of the profession. They had attempted the revision of some of the bylaws, but certain parts had not been very favourably received. He believed that the objectors and the Council

Digitized by Google

would prove to be more at one than was at present supposed. The whole question was to be gone into again; and, he did not doubt, there would be ultimate satisfaction to all parties. The arrangements for the Sketch Book had been altered. For the past eighteen years Mr. W. G. B. Lewis had been a most loyal friend to it. It would now be the duty of Mr. Gerald Horsley, Mr. Theodore Fyfe and Mr. Curtis Green to carry on the great tradition that had been established. Another feature was the formation of the athletic club; this was perhaps the most remarkable illustration of progress in their entire history; moreover, the membership was increasing daily. It showed the amount of interest which athletics commanded. The annual sports will take place on June 5 at Stamford Bridge, where excellent sport would be afforded, and it would be a great help if everybody, both members and friends, would attend. The Association had during his term of office received the promise of a studentship amounting to about 150*l*., which was a matter of very considerable importance. If it was carried through it would be a very great assistance to them. The youth of the Association was its greatest asset. The older members ought to try and help things that are being started, and generally take a keen interest in the affairs of the Architectural Association. They had a very large number (including about half of the day school) of their members connected with the Territorials. The occasion of the annual dinner was a suitable one for thanking the Council for their assistance to him, and also for thanking the staff, with Mr. D. G. Driver at their head. At one time it had seemed a relief to him to think of the time when he would get out of the chair. But now he was beginning to feel that when he had passed the chair he would have passed beyond one phase in his professional career, and to have joined the senior ranks. It had been two years of great interest to him, and he had come to the conclusion that even two years was scarcely long enough in which to learn everything that is to be learnt in order to keep things going. The new president, Mr. Henry Tanner, jun., was well known to everybody, for he had held office during six years. No one was better qualified to carry on the work, and the Association would be in the very best of hands. Mr. Cave concluded by thanking everybody for their toleration, and wishing the Architectural Association the very best success and a long life.

Mr. Henry Tanner, jun., in proposing the toast of "The Royal Institute of British Architects," said it was one certain to be received with the greatest enthusiasm. The relations had always been most cordial. The parental interest of the Institute had been shown for many a year, not only in moral support, but financially also. Their donations had been most useful, especially the contribution to the building fund whose funeral had just been alluded to. They must mention also those to the Sketch Book and Architectural Museum. The debt on the side of the Association might well seem a long one, but if the Institute gave them money, the Association gave in return men who rose to high office. Looking at the Council for next year their Mr. H. T. Hare and Mr. Guy Dawber were both on the top. Mr. Cave, their retiring president, who had served them for so many years, would go just as far in the Institute, and be just as popular. There was hardly any need to lay any stress on the wide influence of the Institute, as was shown by the multiplicity of subjects they are consulted upon. One of them was the London County Council Bill, 1909—on this subject Mr. Ernest George had published a very excellent letter, with which he was in agreement. Architects could not approve of much of that Bill; they had no wish to be scheduled, and he believed their point of view would finally outweigh the London County Council's. The Institute were to be congratulated on their financial position with its reserve of 26,000*l*. He might express a hope that that would not be kept intact long; he would like to see them housed in a worthy building of their own. Probably he was preparing trouble for some architect. It was hard enough to design for an ordinary client; he scarcely dared think what it would be like to do so for a company of architects.

Mr. Ernest George, P.R.I.B.A., said that the Institute had always been in entire sympathy with the Association and had always had the greatest regard for it. The bond was that of work in common. The achievements of the Association were most interesting. Young architects now possessed fine opportunities for training which were unknown when their elders were young. There were the schools and a capital system of visits to old buildings, works in progress, builders' workshops, and other places for getting a knowledge of materials. In his day students joined the Royal Academy schools for the fun of competing for the medals. They attended lectures by the champions of the Gothic and Classic schools. When Mr. Phenè Spiers returned from Paris, the idea of a school for architecture took shape. The teaching now obtainable was undoubtedly fine, but it was to be hoped it would never take the place of apprenticeship, which was very profitable, and always will be. The erection of a farmhouse taught as much construction as the erection of a temple. Something more was wanted than an answering of economic requirements. The Association Sketch Book was admirable, and equally so was their selection of officers. The Institute appreciated the fine men sent up to them, and they formed a strong body.

Sir A. Brumwell Thomas proposed "The Visitors," who made a long and distinguished list. First came Sir W. B. Richmond, R.A., who was to respond. This artist was known to all for his decoration of St. Paul's. It might be said with all sincerity that future generations of workers in mosaic will have reason to be grateful for the spirit of thoroughness he brought to the study of that tremendous problem. The care with which he investigated the effect of various colours placed in opposition, and how he obtained his colour scheme will be remembered by all. Sir William Richmond might well say with Leonardo da Vinci, "Thou, O God, dost sell to us all good things at the price of labour!" Mr. T. G. Jackson has brought great scholarship into his practice of architecture. After a distinguished University career he became a pupil of Sir Gilbert Scott's. He is to be credited with an enormous number of collegiate and other works which have given very great pleasure to the large number of his admirers. The President of the Institute would always be welcome as being one who always attended their functions. It might be necessary to remind future presidents of this precedent. Mr. E. A. Abbey, R.A., commenced his career as an accomplished black and white illustrator; he had developed into a most decorative painter. Architects admire his works, except in one very important particular, which was not past remedy in the future, viz. that they always go across the Atlantic. Mr. Solomon had to his credit a long list of ideal paintings. Professor Blomfield was looked on as one of the authorities on education, and therefore of special interest to the Association. On one point the Architectural Association might well make a departure. They pursued a course of study up to a certain point, and then left the students to look after themselves. But really the Association should take on for a year or two longer those who are anxious to pursue their preparation, and so take advantage of their enthusiasm, and make it more national. Mr. Greville Montgomery, M.P., was to be congratulated on the success of his building exhibition. To-day the pageantry of the past was popular. And it might be thought that he had just been making such a pageant; though really his review was of the characters of to-day, of old friends and distinguished artists who have this one aim in common "that they pursue truth together."

Sir W. B. Richmond, R.A., said he preferred to talk about other people than himself, but the present was an opportunity for saying something which he had been wanting to say, and he was encouraged to do so by the knowledge that in all probability few of those present had travelled the world as he had done. They might not have observed, and they might not know that one of the great points of ancient architecture was that it was always coloured. One gentleman in discussing this subject exclaimed, "Oh! I prefer it bare." Sir William asked to be allowed to mention some of the ancient architecture which he had himself seen that had been coloured. There was the Temple of Selinus destroyed 300 B.C., in which colour was employed so beautifully by the architect using grey, blue, black and brown, that, while it in no way interfered with the structural portions, it seemed to have performed the act of embracing the sky. It was used with wonderful skill in the propylæa and temples of Athens. He had seen it in Egypt. Until a certain period there was no building in Great Britain which did not receive colour upon the majority of the surfaces. The prevalent idea of non-colour is entirely a modern one and dates from the days when the arts became divorced. The painter said to himself "I will stand upon my own legs, and I will put my pictures in frames." The architect said, "I am the skeleton and I want no colour." That is a mistake. No one wants the adoption of unrestrained colour over anything. But what is wanted is some means of coalition in the very principles of education. Supposing an architect knows at the beginning his building is to be aided by sculpture and colour. At the moment of the conception of his plan the painter and the sculptor should be called in, and for very obvious reasons. The architect will restrain them from vagaries, and

Digitized by Google

perhaps they will restrain him from going beyond instructions. We have a right to look to the millennium when there will be absolute coalition between architect, sculptor and painter—it will come at last. The first move must come from the mistress of the arts if it is desired to make the best of the buildings, and to get the utmost out of them. But said Sir William, "don't get bad sculpture because it is cheap, leave a capital plain rather than badly carved. If you can't afford to pay the price of good decorative painting, don't go to a firm which turns out things ad nauseam." Architects have got the matter in the very palms of their hands. They should seek out young earnest sculptors and painters, and train them to do their will, while appealing to them sympathetically. In time there will arise a school which (by beginning when man is at his best—in his youth) will be equal to anything the world has seen, and it will be a national school as great as has ever been known.

THE SOCIETY OF ARCHITECTS.

A MEETING of the above Society was held on Thursday, May 13, when Mr. G. Topham Forrest (Member), architect to the Northumberland education committee, read the following paper on "Secondary Schools."

A little over a year ago I had the honour of reading before this Society a paper on the "Planning of Elementary Schools," dealing with the subject from the standpoint of Part III. of the Education Act of 1902. To-night I propose to deal with Part II. of that Act, where it is enacted that local education authorities shall consider the educational needs of their areas and take such steps as seem to be desirable to supply or aid the supply of education other than elementary.

Before giving the matter serious consideration, many authorities deemed it advisable to devote their energies to the very important question of elementary education, with the result that a considerable amount of improvement has been effected in the sanitary conditions and equipment of our public elementary schools. The time, however, has now come when secondary schools are receiving due attention, and the present appears to be a good opportunity for the consideration of the various matters connected with the planning and erection of these buildings.

Having been engaged exclusively upon school work since the passing of the Act of 1902, I propose to-night to touch only on such points as I can establish from my own experience and observations (advisory and otherwise), regarding it as a duty to do this little to advance a subject on which, I feel certain, much practical information and enlightenment is still needed.

The education question has now become all-embracing; the country's education bill runs into millions. Wastage in the past has been enormous. Wastage in many ways, on buildings and furniture which are now unsuitable, and on schools which err in some hygienic provision, so that costly remedies have had to be found.

The conditions under which education is now carried on are so vastly improved that any attempt at a general sketch of systems or organisations would be out of place here. In most competitions for secondary schools and where work is entrusted to architects in private practice, fully drawn up rules and regulations are now invariably issued by local education authorities, and intending competitors are informed as to the methods of classification, the sub-divisions of classes and questions of organisation, so that the architect before commencing with his plans has a clear idea of the law and conditions under which education is carried on, under the authority to whom the plans have to be submitted. He can study, therefore, very closely the question of routine and organisation in that particular district, which is (needless to state) of the utmost importance in securing the best possible plan.

The subject of this paper being capable of indefinite expansion, some limitation is desirable, and therefore I have endeavoured to make the character of it as practical as it is possible to do so, adopting the principle that it is better to thrash out in detail one or two of the more important headings, rather than to indulge in a superficial skimming over of them all, as is generally adopted, without of course plunging into the thousand and one scientific, technical and artistic questions which must be solved by the architect in each case.

Matters relating to the size of cloakrooms, the amount of hanging space necessary for each scholar, the number of closets required, &c., have already received their quota of discussion and need not be repeated here. These and similar matters are dealt with fully in the building rules issued by the Board of Education. These rules should always constitute the architect's vade mecum, although committing them to memory must be regarded only as a means to the end, as efficiency can only be acquired by practical everyday experience.

The school architect has to be thoroughly efficient in the principles of planning, how to get the accommodation required squeezed into the most suitable and economic plan for the money at his command, the choice of good building material, up-to-date science fittings, a good system of heating and ventilation, and the latest in gas and electric light illuminants. New systems of warming and ventilating buildings appear every year. Science fittings of a few years ago are now obsolete. Every month sees some new form of gas or electric lamp put on the market; and this is the era of ferro-concrete. Therefore, I say, these matters must *not* be allowed to stagnate, but must be kept moving. Our books must be continually open in front of us, otherwise our schools will be hopelessly out of date in a few years.

The discussion in the following paper of some specific systems of heating, &c., also details of fittings, &c., is made from an independent and unbiased study of their merits, and without any interest in advertising their excellences or their defects.

The term "secondary school" is of wide application and covers educational institutions of very different aim and type. It is applied to the city grammar school, the city high school, the modern commercial or technical school and the residential school. Strictly, the name should be confined to those schools which educate pupils who have passed the primary or preparatory stage, and whose age is approximately thirteen to eighteen. But the majority of secondary schools have preparatory departments and undertake the education of the young from the age of seven.

Secondary schools are divided into two classes (1) residential or boarding schools, (2) day schools. In the former, for a considerable part of the year, the school performs the double function of a school and house; and in the latter (which is the subject of this paper), the school merely shares with the home in the process and responsibility of education.

In dealing with the subject, I have adopted the following arrangement. First of all to give some consideration to the question affecting the plan generally, and of the extent of the accommodation required, the use and purposes of the different rooms, and the form, dimensions, &c., that have been found best adapted to serve the purposes, the best types of science fittings and desks, suitable systems of heating and ventilation, and the latest principles in artificial lighting. Complete plans have been commented upon, but constructional details have been as far as possible avoided.

In selecting the schools for illustration on these walls, great care has been taken to try and show the various types of buildings erected by different education authorities, and to what extent perfect organisation of the school depends upon the plan. These illustrated are all recently designed buildings, and embody the latest developments in secondary day school planning.

It is not suggested that they show in all cases an ideal arrangement, or that they are merely models to be copied; they show how things are being done, but not necessarily how they should be done. There can be no ideal plan made to suit all requirements, as the organisation of the school materially affects the arrangement of the buildings, and districts and centres vary tremendously.

Site and Aspect.

The question of site is an all-important one. As the hygiene of a school really commences with the site, the importance of securing a good one is obvious. I think, however, that enough has already been written regarding the ideal position for a school site which, as far as actual experience goes, is not of much practical value. I propose, therefore, to pass on to the consideration of a few points which concern themselves with preparations for actual building. Very often the site is fixed upon before instructions are given to the architect, but those interested in this question should note carefully the following points:—

It is very desirable that the architect should ascertain as far as possible the probabilities of any damage to the surface of the site by mineral workings, in order that he may, in planning the buildings, take into consideration the question of the foundations should the circumstances appear to call for special treatment.

(To be continued.)

NOTES AND COMMENTS.

It is but fair to the Corporation of the City of Bath that notice should be taken of their reply to the charges that have been made against them in respect of the proposed alterations in Bath Street. The Corporation say:—"That the Bath Street houses (with the exception of the corner house facing Stall Street) are not now and never were the property of the Corporation; that the Grand Pump Room Hotel is in the hands of lessees for a term which will not expire for thirty-three years, apart from a new agreement now entered into for the extension of the term; that the enlargement of the hotel is desired by the lessees, who and whose predecessors in title have kept the hotel closed for more than six years; that the Corporation give their assistance to the scheme, believing that it is in the interests of the city so to do, the continued non-occupation of the hotel being an injury to the city and a deprivation to all those invalids who require treatment and accommodation without exposure to the open air; that no pecuniary profit on the transaction is being made by the Corporation, the increased rent being balanced by the postponement of the reversion; that the business took five years to negotiate; that the agreement was sealed a year ago; and that the utmost publicity has been given to the matter throughout." They also assert that Bath Street is not a portion of what is commonly understood as eighteenth-century Bath, nor is it a "part of the scheme for the building of Bath," nor has it "extraordinary historical associations."

The Royal Commission on Ancient Monuments in Wales and Monmouthshire has held its first meeting in the Principality at Cardiff, and has collected already some interesting facts with regard to the existing antiquities of that district of Wales. The need of such a Commission and of the assistance of the Government in the preservation of ancient monuments is shown in the effect of the weather on the great cromlech of St. Nicholas. The capstone of this, the largest in the county, is cracked across, and one side is subsiding. On the other hand, the effect of man's spoliation is seen in the south wall at Caerwent, which, it was stated in evidence, is the finest and most imposing piece of Roman work in the south of Great Britain, being 22 feet high and 10 feet 6 inches thick. This has been brought to a dangerous condition by the removal of the faced stone near the plinth, probably for building purposes. There seem to be a good many tumuli in the district around Cardiff, and although many have been opened, some are still unopened. The data regarding the tumuli are not, however, sufficient for any scientific classification. Roman remains are numerous, and excavations have been made at Cardiff, Caerleon, Caerwent, Llantwit-Major, Gelligaer, and Dowlais.

ILLUSTRATIONS.

OXFORD COLLEGE SERIES. QUEEN'S.—INTERIOR OF CHAPEL—INTERIOR OF LIBRARY.

The illustrations given this week of Queen's College are in continuation of those in our issues of April 16 and April 30, with the historical account of the College by the Provost, Dr. Magrath.

NEW BUILDING FOR THE GOVERNMENT OF VICTORIA, AUSTRALIA.

The basement contains store-rooms, strong-room, furnace chamber, &c., and is approached by a separate entrance in Melbourne Place. From this last entrance is provided an electric goods lift between the ground and the basement floors. The ground floor is wholly occupied as an exhibit hall, and is fitted up with mahogany showcases. There are two entrances to this floor, the principal one being in the Strand and the secondary, or office entrance, in Melbourne Place. A passenger lift is arranged close by this last entrance, which serves all the floors in the building. The first floor is occupied by the Secretary and his staff, the second floor by the Agent-General and his secretary, the third floor by the accountant, &c. The fourth floor is arranged as an exhibit room for mineral products, &c., and the fifth floor as a reading room. The sixth floor is constructed in the roof, and contains ample space for storing Government papers and books. The floors, roofs, and staircases are constructed of fireproof materials. The joinery consists chiefly of mahogany. Victorian marble is used for the hearths and surrounds of stoves. Lavatories are provided off the staircase for all the principal floors. Low-pressure radiators, electric lighting, and intercommunication telephones have been installed throughout the building. The building is faced with Portland stone, and the roofs covered with green slates with copper finishings, &c. The total height of the building is about 120 feet from the pavement to the top of the small dome, upon which stands the figure of "Progress," modelled by Mr. F. W. Pomeroy, A.R.A. Mr. Alfred Burr, F.R.I.B.A., of 85 Gower Street, is the architect. He has also designed the completion of the Strand block of which the Victorian Government Offices form the western end.

NEW OFFICES FOR THE GRAND TRUNK RAILWAY OF CANADA.

These premises have been erected in Cockspur Street, S.W., by the Grand Trunk Railway Company of Canada, to serve as their West End offices. Their main office occupies all the ground floor. The remainder of the building has been arranged as independent offices, and for these tenants are now being sought. They are reached by staircases from Cockspur Street and Warwick House Street. The main office is 17 feet 6 inches high, with black oak panelling up to 10 feet 6 inches, and a frieze over by Mr. F. Brangwyn, A.R.A. The front is in Portland stone. The work has been carried out by Messrs. Leslie & Co. from the designs of Sir Aston Webb, R.A.

NEW BUILDINGS FOR THE UNIVERSITY OF CAMBRIDGE.

These buildings, opened by the King in March 1904, have been erected from the designs of Mr. T. G. Jackson, R.A. The Sedgwick Memorial Museum has been built partly with a fund raised shortly after his death to commemorate Adam Sedgwick, Woodwardian Professor of Geology in the University of Cambridge. The building stands on a site purchased from Downing College for University purposes, and is an L in plan, facing Downing Street and Downing Place. It contains on the ground floor two large lecture rooms, working rooms, and a museum of comparative geology. Two staircases contained in projecting towers rise from storey to storey to the top of the building; but the principal entrance to the great museum, which occupies nearly the whole first floor, is by an external staircase in the interior court, which divides at the lower part into two sweeps, at the foot of which are a pair of cave-bears and a pair of primitive bisons, forming the finish of the balustrades on either side. The great museum is fitted with high cases projecting at right angles to the walls between the windows, and table cases elsewhere. Down the middle are arranged the great saurians and skeletons of extinct animals, and at the south end is a board room, with a private room for the Professor adjoining. In a niche between two arches in the centre of the museum is a bronze statue of Professor Sedgwick, the last work of the late Onslow Ford, R.A. The second floor is occupied by numerous museums and laboratories, and by a library which is handsomely fitted with oak, for which part of a gift of 2,000*l.* from Dr. Latham, the late Master of Trinity Hall, was made available. The builder was Mr. Sindall, of Cambridge, and the clerk of works Mr. Robert Edwards. The carving is by artists from the staff of Messrs. Farmer & Brindley. The fireproof floors and other constructive ironwork is by Messrs. Homan & Rodgers, of London.

SOUTH MIMMS CHURCH, MIDDLESEX. From a Sketch by ADRIAN HARDMAN.

BRUGES AND THE NEIGHBOURHOOD.*

(*Concluded from last week.*)

FORMERLY connected with the sea by means of the Zwyn, an arm of the North Sea now long since dried up, in the thirteenth and fourteenth centuries Bruges was the principal port of Europe. It was the great manufacturing centre of the north. The great cities of the Low Countries were the industrial capitals of the north and west, and equal in importance with Florence, Venice and Constantinople in the south and east. They imported wool, largely from England, and manufactured it into cloth. This was their staple industry, and as the centre of the Hanseatic League carried on an extensive trade with Europe and the East. In the Middle Ages Belgium in the north and Italy in the south formed the commercial and artistic centres of mediævalism. This is shown in the character of the buildings and architecture. In Belgium we do not find the magnificent palaces, the marbles and mosaics of Italy, but cloth halls, town halls, merchants' houses and simple brick dwellings, typifying the commercial pursuits of a great trading community. A country which could produce artists of the genius of Memlinc, the Van Eycks, Rubens, and such masterpieces of architecture as the Cloth Hall at Ypres, Hôtel de Ville in Brussels, and many other buildings too numerous to mention, must be recognised amongst the other nations renowned for their art and architecture.

The most perfect piece of architecture in Bruges is perhaps the Hôtel de Ville, which stands in the centre of the Place du Bourg on the south side. It is a beautifully proportioned Gothic building, dating from the year 1376, and was erected by Count Louis of Maele, probably finished about the year 1420. The architect is supposed to be Jean de Valenciennes, but it is not known for certain. The treatment of the windows is a common feature in Bruges, the outer mouldings running up between the storeys, forming a kind of panel treatment in between. It is found in the brick gables and other buildings, and this may probably have served as a model. The niches between the windows contain statues of the Counts of Flanders. These are not the original ones; they were destroyed by the French revolutionaries in the eighteenth century. The whole of the upper storey is occupied by the great hall, which has a very fine open timber roof. A photograph of Mr. Curtis Green's charming drawing of the Hôtel de Ville shows the whole façade of the building. On the right is the Chapel of the Holy Blood, and on the left is the Maison de l'Ancien Greffe. The latter is a very ornate semi-Renaissance and not particularly interesting building dating from 1535. It has been restored, and is used now as a court of justice. The fireplace in the Court-room, which formed part of a former building occupying the same site, is an interesting piece of Renaissance work erected to commemorate the battle of Pavia, which resulted in the declaration of the independence of Flanders. The lower part is of black and white marble, and the overmantel is of oak. The central figure is that of Charles V. of Flanders, and on either hand are statues of his ancestors, parents and other members of his family. It has been restored. The Chapel of the Holy Blood, to which I have already referred, is the chapel in which is deposited the vial which tradition says contains some of the water in which Joseph of Arimathea had once washed the body of our Lord. This relic was brought from the Holy Land in the twelfth century by Dierick of Alsace, Count of Flanders, cousin of Charles the Good, and deposited in the old chapel which Baldwin of the Iron Hand had built. This relic has been associated in a remarkable way with the history of Bruges. During the troubles with Ghent in the fourteenth century it was lost, but later was found in one of the waterways close to the Beguinage. It was hidden during Reformation times, and only restored to its present resting-place in 1819. This chapel is a building of two storeys, the lower one being the crypt of St. Basil, probably the oldest building existing in Bruges. The upper chapel was rebuilt in the fifteenth century. At the time of the French Revolution it had fallen into great disrepair, and was restored in the nineteenth century. The portal and staircase of the chapel are on the west side of the square; they date from the sixteenth century and, like the chapel itself, have been restored. The statues are of bronze.

A photograph of a portion of a bird's-eye view of Bruges, the work of Marc Gheeraerts in the year 1562, is particularly interesting, as it shows the ancient Bourg as it existed at that date, with the group of buildings on the south side, including the Hôtel de Ville, the Chapel of the Holy Blood, and on the left the Maison de l'Ancien Greffe. The old church of St. Donatian then occupied the north side of the square. This building, originally founded by Baldwin, was pulled down in the eighteenth century. Its place is now taken by the fish market. To the right is the belfry and the old Cloth Hall, a fourteenth-century building which has long since disappeared. The River Roya can be traced in its course between the belfry and the west side of the Bourg and along under the old Cloth Hall. It follows the same course still, but, as already mentioned, has been built over since. The belfry, occupying the central position in the market place, is the most conspicuous structure in Bruges. In nearly all the principal Flemish towns the belfry is the central and dominating feature, towering up sometimes many storeys over the surrounding buildings. In Flanders the belfry was the symbol of civic liberty. The sounding of the bell in the Middle Ages was a call to arms, and of many a

* A paper read by Mr. C. Wontner Smith before the Architectural Association on April 30.

Digitized by Google

tragic scene has the belfry at Bruges been the silent witness during the 600 years it has stood in the old market place. It is, perhaps, the most interesting of all Flemish belfries. Poets and writers have vied with each other in praising the beauty of its outline and the charm and richness of its sweet-toned bells:—

> Low and loud, and sweetly blended,
> Low at times, and loud at times,
> And changing like a poet's rhymes,
> Ring the beautiful wild chimes
> From the belfry in the market of the ancient town of Bruges.

Its architectural merits are, however, another matter. It is a strange conglomeration of storeys and styles. It has been destroyed three times, has been added to and altered; its very height gives it a dignity which its architectural merits fail to do. The belfry has a strange history. No doubt the original structure was built in the days of the first Counts of Flanders, and was constructed of rough stone, like other buildings of the time. It was totally destroyed in the thirteenth century and afterwards rebuilt, the two lower storeys dating from this period. The octagon was added in the fifteenth century and the parapet 100 years ago. There is another tower in Bruges more striking than the belfry and a far finer piece of architecture. I refer to the tower of the church of Notre Dame. This dates from the thirteenth century and is of magnificent proportions. It is built of brick and rises to a height of just 400 feet, measuring to the top of the spire. The Late Gothic portal of the north side is a very charming little piece of work; nestling at the base of the tower it looks absurdly small in proportion. The cathedral of St. Sauveur close by has been much spoilt by later additions. The transept and the group of chapels round the choir are quite the best parts. The tower is comparatively modern. By far the most interesting church in Bruges is the Church of Jerusalem or Holy Sepulchre. This is quite a small building, erected at the beginning of the fifteenth century by two brothers named Adornes. The plan is most peculiar and quite unique. The nave has no aisles. The sanctuary is underneath the tower, which is at the east end, and is reached from the nave by two stone staircases 10 or 12 feet above the rest of the church. The exterior is as quaint as the interior. It is built of brick, and the tower above the roof-level becomes octagonal. There are two small angle turrets at this stage in front, but at the back the walls are simply sloped off. The whole is surmounted by a wooden fleche, terminating in a large golden globe. The grouping and general appearance of this little building is extremely pleasing. It might be called, perhaps, the "Miracoli" of Bruges.

But, however interesting, it is not the churches which form the chief attraction of these Belgian cities; the old brick houses, with the stepped gables and traceried windows, are their chief charm. Until about the fourteenth century the houses were probably built of wood. As the number of the inhabitants increased and better buildings were required brick was more generally employed. Nearly all the public buildings in Bruges were erected in the fourteenth and fifteenth centuries, and the greater number of them are of brick.

The Flemish bricks are unequalled in colour and texture. They are small in size, very uneven in surface, and the graduation in colour has a most charming effect. The windows are generally grouped together in recessed panels; the outer mouldings enclosing them run right up to the top storey. The windows themselves are square, sometimes having stone lintels and dressings, but are more often of brick, the space between the head of the windows and the top of the enclosing arch being generally filled with tracery. When mouldings are used they are simple in character, but the plain chamfer often sufficed. The later examples are rather overloaded with detail and tracery, but many of them are well designed; the variety of treatment is wonderful. Some of the most noted of the old houses and halls still remaining in Bruges are the halls of the merchants of Genoa and Spain, the Maison des Orientaux, which was the residence of the great traders of the Hanseatic League, the Gruthuise, Ghistelhof and many others. One of the most charming little buildings, for its design and general proportions, is that known as the "Poorter's Loge." It was built in the middle of the fourteenth century, and was used then as a kind of mediæval club house.

Bruges in the Middle Ages must have been a city of turrets and spires. Many of them have, alas! disappeared, but there are a few still remaining, and of these a very good example is the one behind the "Poorter's Loge." There is another one close to the Quai du Rosaire, at the back of the Hôtel de Ville. I should just like to mention another interesting building in Bruges, and that is the Hospital of St. John. This building was founded in the twelfth century and still serves the same purpose. It forms a very picturesque group opposite the church of Notre Dame, and in it are to be seen some of the best examples of Memlinc's work. It is rather difficult to get a good view of, as the streets are narrow at this point. One of the most interesting parts is that close to the canal. To the right of the old thirteenth-century gateway, now built up, is the chapel, and beyond it the present entrance and some later additions which have been recently restored. The ramparts which formerly surrounded Bruges have been pulled down, and of the old picturesque gateways only three now remain.

Those who have been to Bruges have no doubt been struck by the number of small Renaissance doorways to be seen in many of the side-streets, set in little gable ends of brick. These are the entrance doorways to the almshouses or "Godhuises," which were founded in the seventeenth century. After the troubles with Maximilian, Bruges became almost depopulated, and owing to the silting up of the Zwyn, which formerly connected it with the sea, its position as a manufacturing city was considerably affected. Most of the weavers left Bruges and settled in Antwerp and other places, and at this time Bruges became the home of many of the neighbouring religious houses, who erected convents and hospitals in all parts of the city. Many of the doorways are well designed, and have over them in some instances niches containing figures. There are many other things I should like to say about Bruges, but it is impossible in a short paper as this must be to do more than make a passing reference to the many interesting buildings which it possesses. I fear I have treated the subject very inadequately, but as I want to say something about the other towns we visited, I must pass on. A few hours were spent at Damme and Courtrai, the former at one time the port of Bruges, and a most interesting place. However, I can only mention the more important towns. Like Bruges, Ypres was in the fourteenth and fifteenth centuries a very important and flourishing town, and one of the principal centres of the manufacturing trade. The chief interest lies in the group of buildings of which the Cloth Hall is the central feature. The Cloth Hall at Ypres is the finest in Belgium. Its enormous length, the dignity and simplicity of its design are most impressive, and seen from the market place with the church of St. Martin rising in the background, it forms one of the finest groups of buildings to be seen anywhere. This Cloth Hall was commenced in the thirteenth century, and was not completed till 100 years later. The main façade is 335 feet long, and the Cloth Hall proper occupies the upper storey. These old Cloth Halls of Belgium are a distinctive product of a commercial community, the legacy left by the trading republics of the Middle Ages. It is commercialism embodied in building, and they remain to-day monuments to the enterprise and genius of these old Flemish burghers. The building at the east end of the Cloth Hall is called the Nieuwerk, a Renaissance structure dating from the year 1620. The upper floor of the Cloth Hall consists of three long galleries with open timber roof, containing frescoes representing incidents in the history of Ypres. Inside the courtyard are two very interesting wooden gables with large recessed windows in which there is some old glass, and a picturesque timber passage-way supported on wooden cantilevers.

Ypres possesses in addition to its Cloth Hall, the exceedingly fine church of St. Martin, formerly the cathedral of the district. It is of very ancient foundation, and dates from the thirteenth century, erected on the site of a much earlier church. The western tower is a lofty and beautifully proportioned piece of work, later than the church itself. It has never been completed, but the base of the stone spire, with which it was originally intended to be finished, just shows above the roof. It was designed by Martin Utenhove, of Malines. Portions of the church are now being restored, and there is a talk of completing the spire, but I think it would be much better to leave it alone. It is built of brick and stone, and is nearly 200 feet high. The interior of the church is equally interesting, the columns and arches are of a darkish green stone, and the choir, which has no ambulatory or chapels, contains some good Renaissance woodwork in the shape of stalls and confessionals. The font, at the west side, is a charming piece of Renaissance work. It is of bronze, and the font-cover is attached to a wrought-iron bracket on the wall. Beyond these two buildings, Ypres contains nothing of very great interest. There is one other building, however, that I should like to mention, and that is the

Digitized by Google

Boucherie or meat market, which stands in the south-west corner of the Grand Place. The lower storeys are of rough stone work, and date from the thirteenth century. The upper part is of brick, with the typical Flemish gables and traceried windows. Of Ghent I do not propose to say much. I was only there a few hours, and consequently know very little about it. Like other Belgian cities, Ghent is being modernised, but some of its old buildings still remain. Time will not permit me to do more than just mention one or two of them. The church of St. Nicholas, one of the oldest buildings in Ghent, claimed a good deal of my attention. Unfortunately the interior has been greatly modernised, but the exterior is much as it was; in fact it has been improved considerably since the houses which formerly stood all round and against it have been removed. It piles up magnificently, and looks equally well from any point of view. Though not particularly attractive outside, the cathedral at Ghent has an impressive interior. Apart from its architecture, its chief interest lies in the fine examples of Vandyke's works which it contains. Mention must be made of the Renaissance sacristy, which is a very charming piece of work. The Hôtel de Ville, a building of the florid Gothic type, has been considerably restored. It has several interesting features, the best being perhaps the rectangular Gothic staircase, with pierced balustrades and brick-vaulted roof running up to the first floor.

Before passing on to Oudenarde in conclusion, I should like to mention the group of old buildings on the Quai aux Herbes. The well-known Skipper's House is one, and perhaps the best of its kind in Belgium. It was erected in 1531, and is now being restored. Next to it is a Renaissance house, and beyond a very early building, used as a granary in the twelfth century. It reminds one of the lower part of the Boucherie at Ypres, the character of the stonework and general design is somewhat similar. The architectural interest in Oudenarde centres round the Hôtel de Ville and the church of St. Walburga. The latter dates from various periods. The tower is of magnificent proportions, and possesses, incidentally, a really musical peal of bells. The Hôtel de Ville is a small building, erected in the Late Gothic period, and although rather florid and overloaded with enrichment, is a very good piece of work of its date. Inside there is a well-designed Late Gothic chimney-piece, and an oak screen, the work of Paul von Shelden. During the restoration of the central turret about ten years ago, Mr. Ellis Marsland, who was then touring in Belgium, seized the opportunity of taking a series of photographs while the scaffolding was there, and these form a unique collection of views of the different storeys right to the apex, including the lead figure above the crown.

Mr. H. D. SEARLES-WOOD, in proposing a vote of thanks to the lecturer, said it had been enjoyable to see views of buildings familiar to most of them, and which recalled to him his first tour abroad. The opinion formed then was that Belgium made an interesting change in the usual programme of excursions, but it was a tour which could be taken by anybody, and did not require guidance. In their annual excursions members of the Association had access to buildings which were not open to the general public, but in Bruges they were not privileged in that way. As far as the country districts of Belgium were concerned it was very significant how very little architecture there was beyond the fortified walls of the towns. He presumed the reason was that the country, being open to invasion, was too much disturbed to allow of important buildings being erected.

Mr. W. CURTIS GREEN seconded the motion, and remarked that lectures of the kind were valuable, because they saw illustrations of mediæval buildings which helped thought. That period of architecture was nearer to them than any other, and it seemed to him that the buildings could be dissected, and their points in construction found out; yet when they had discovered that they knew as much as the mediæval builders, and that they could do even better work, they felt they could not do what the mediæval men did, since their work lacked the same charm.

Mr. R. P. OGLESBY attributed the charm to be found in mediæval buildings to age and the time given to their erection.

Mr. F. DARE CLAPHAM hoped the lecture would set two precedents, (1) that the retiring hon. secretary should always read a paper when about to quit office; and (2) that occasionally they had a paper written on the annual excursion. Such a paper as that he was sure would be most interesting to those members of the Association who for various reasons could not take part in the gatherings. Many of the members knew very little about their own country, and on the annual excursions in England buildings were visited which it would be impossible to see privately; the value therefore of papers similar to the one they had heard that evening was apparent.

Sir A. Brumwell Thomas, Messrs. Theodore Fyfe, S. Flint Clarkson, F. Winton Newman, and H. W. Brittan supported the vote of thanks.

Sir A. BRUMWELL THOMAS on behalf of the members offered the thanks of the Association to Mr. Walter Cave, the retiring president, and Messrs. Curtis Green, Louis Ambler, W. Wonnacott, and A. Needham Wilson, the retiring members of Council.

The motion was carried by acclamation.

PICTURES AND THEIR ARTISTIC ENJOYMENT.

By P. WALTON HARRISON, M.S.A., P.A.S.I.

"I KNOW what I like!" is a remark almost certain to be heard at any exhibition of pictures, and the tone of voice in which it is usually uttered leaves little room for doubt that the speaker at least is convinced that "what I like" is certainly not less worthy of admiration than what anybody else likes.

It may happen that some friend whose knowledge of art is not confined to "knowing what he likes" is standing by, and ventures to question the merit of some picture singled out by the speaker for special approval; but, if so, his objections are promptly met by the well-known assertion that "De gustibus non est disputandum!"

Now if any artist is sufficiently in earnest to desire that good art should be appreciated and bad art condemned, it is his positive duty not to allow those who know nothing about art to take refuge behind this false and flattering old proverb. Taste is a matter that admits of discussion; one man's taste is emphatically not as good as another's.

Architecture, sculpture, painting and music are but different dialects of the universal art language, and should express, each in its own sphere, some beautiful phrase of nature. Every day vulgarities, and coarse strength of language are intelligible even to inattentive ears, but refinement and grandeur of language come to us only as the reward of some study of the subject.

The average public which pays its annual shilling at the turnstiles of Burlington House "does" the exhibition and comes away with a headache, due mostly to mental indigestion. Not knowing what is good and what is bad, what is worth looking at and what is not, most of the visitors have to look once at least at every picture on the walls, and are constantly on the strain not to miss any that they may afterwards be told they ought to have seen and admired.

The physical and mental effort involved in seeing an exhibition in this way is exhausting, and hence the almost inevitable headache of those who "only know *what* they like." But those who know also *why* they like certain pictures better than others, and have art knowledge enough to recognise good pictures at a glance, look only at them, and consequently come away pleasantly stimulated by their two or three hours' stroll through the Academy rooms.

How many of us admire a landscape for no better reason than that last year we wandered up that valley, or climbed that mountain-side, or loitered away a summer's afternoon on that shore; or are interested in a picture mainly because it shows us a particular place that we purpose visiting? How many of us again are attracted to a picture simply by some humorous incident, some silly sentimentality, some simpering face with eyes of superhuman size; whilst, whether a picture is well-composed, well-drawn, well-painted, whether the colour is richly or delicately harmonious, whether, in a word, the language in which the ideas of the painter are expressed is forcible or refined, what does it matter to us? Unable to understand, we are unable to enjoy.

To be able to derive artistic enjoyment from any work of art one must have the power in some measure of appreciating technical excellence, and be able to apprehend the aim of the artist in each picture that he paints.

All art being but an echo of nature, a knowledge of painting must necessarily quicken our perception of natural beauty, and so add immeasurably to the sum of our enjoyment. But the reverse does not hold good. Because we are ardent students of nature from the scientist's point of view, we are not necessarily able to understand and enjoy a work of art. To be able to do that we must not only be able to see the aim of the artist in each separate work of art, but must

Digitized by Google

apprehend at least, even if we do not practically understand, the limits within which he is constrained to work by the very necessities of his particular art dialect. If not, though of course able to recognise any special beauty or natural truth which the artist has incorporated in his work, we shall be apt to look for phases of truth and aspects of beauty which could not possibly have been included in the same art effort, and, failing to find them, it will be difficult for us to give ourselves up to the enjoyment of the truth and beauty which the artist has been able to realise.

An experienced painter knows only too well how much he must leave unrecorded in every picture he paints so as to render at all visible that particular phase of beauty to express which the picture is painted; and unless we are able to recognise this necessity, how is it possible for us to enter into his enjoyment? If light, for instance, exists in any remarkable degree in a picture, as it does in many of Turner's works, it is foolish to object that the forms are less distinct and the colours less decided than in Nature; because an artist of Turner's power could certainly have emphasised both form and colour correctly had he chosen to do so, and could have elaborated all details as accurately as any so-called "Pre-Raphaelite." Or if we see great richness and beauty of colour in a picture, as we actually do in most of Titian's works, we must be content with the glowing tones of the flesh and the deep splendour of the draperies and backgrounds, and must not complain of the want of absolutely natural truth of light and distance. Or if we find great elegance of line and ideal beauty of form, as we do in so many of Raphael's works, we ought to be content to tolerate the mediocre and sometimes commonplace colouring, which to some extent is the price that Sanzio had to pay for the very qualities for which we admire him. Again, if a picture shows that the painter has aimed at expressing grandeur, vivid vitality or character, we must not be surprised to find forms generalised or even exaggerated, as Michel Angelo and Rubens have actually done.

It is very far from my desire to deny that it is the duty of each artist to do his utmost to unite all possible excellences in every picture he paints; but if we want to get as much pleasure as possible out of existing pictures we must give up the expectation of finding all the best qualities embodied in any of them. If it should sometimes seem to us as if the great masters had almost scorned some of those art qualities that we specially admire, let us confess that they could afford to do so.

Anyone, artist or not, strolling through an exhibition can pick out the pictures that please him, can say what subjects on the walls are sympathetic to himself. But the man who is content only to "know what he likes" must not lose sight of the fact that the subject selected by the painter is not the sole standard of the merit of a picture as a work of art. The choice of subject shows the man; it is the treatment of that subject which reveals the artist.

Now the beauty or grace or truth expressible in a statue or picture is far more material and emotional than intellectual. In sculpture before anything else we want material form sufficiently beautiful to please the eye, and in painting we want first of all beautiful form, beautiful colour, and picturesque light and shade and composition; and without these fundamental requirements the most elevated ideas, the most refined sentiments, have no art value whatever.

The artists who know most about their art know how difficult it is to draw really well, how seldom a picture is perfectly composed, how rarely a painter is greatly gifted as a colourist, how few painters have much taste, and how unlikely it would be to find all or even most of these excellences united in the same artist, and so they are ever glad to greet real merit of any sort, and are ever the most lenient and appreciative of critics. Fault-finding is easy enough, but mere disparagement of pictures, such as one so often hears at public exhibitions, is the lowest form of criticism. A picture represents often a considerable portion of a fellow-creature's life, and if we say anything about it at all, we should honestly endeavour to see what is good in it, as well as notice its evident faults and fallings short of excellence. What profit or pleasure is it likely that anyone can derive from a visit to an exhibition whose habit it is to criticise the pictures somewhat in this fashion?

"Well, yes, now you mention it, I see that the colouring is rather rich; but how coarsely the paint is put on! It doesn't look bad, you say, from this distance; but just go close to it and see if the paint hasn't been plastered on with a trowel. If that's what you call effective painting, give me an artist who knows how to finish his pictures."

Or in this fashion:—

"Oh! the composition is very graceful, is it? Well, perhaps there is a sort of refinement about the picture when you come to examine it carefully; but you don't mean to tell me you call those dingy drabs and dirty greys good colour?"

Surely one would get far more enjoyment from a visit to a picture gallery if it were one's custom to look rather for the merits than for the faults of pictures, and to criticise them something after this fashion:—

"Yes, the drawing is rather hard, and there is a want of air in the picture, and the colour is not absolutely first rate; but what individuality there is in all the forms, and what fine action in that figure! And how dramatically the whole subject is rendered!"

Or in this fashion:—

"I must admit that it is not easy to define some of the details; but what does that matter when the whole picture is so suffused with light, and when the canvas has been transformed into a vision of lovely colour?"

In all honestly-painted pictures there are certainly some qualities worth notice, if only we have eyes to see them; and the only fair way to criticise a work of art is to look for those qualities which the artist has striven after, rather than for those which he has not attempted to express. If we assume any judgment as to the value of a picture as a work of art, we certainly must not base our verdict on the subject merely, but before calling a picture bad or good we must be able to recognise whether or not the drawing is correct, whether the colour is harmonious or true, and whether the composition is good—that is, whether the lines and general arrangement of form, colour, and light and shade are picturesquely effective.

THE DESIGN AND REQUIREMENTS OF ELECTRIC-POWER WORKS.*

IN all electric-power works it is important to secure a good site, and in searching for a site it is necessary to bear in mind the following:—

Site.

(1) In the early days the works were so small that it made little difference whether the fuel could be unloaded direct or had to be carted, but in our days, when electric-power works are getting of such dimensions and require such an enormous amount of fuel, it is important that every penny should be saved in its handling. A great many works are suffering from the early mistakes made. In many municipal works the site was chosen on account of the Corporation owning the land—often in the middle of well-populated districts—and as the works have grown this bad selection has cost them thousands of pounds. The fuel must be obtainable to-day either by rail or water, preferably by both. If by rail, a switch siding should be constructed; and if by water on the river or canal, a wharfage should be built so that the coal can be picked up by the transporters or cranes from the barges and delivered direct into the bunkers.

(2) There are many works to-day where the necessity for a supply of water for boiler feed and condensing purposes was lost sight of, important as it is.

(3) The site selected should be in such a position that no question of nuisance, annoyance or injunction can give future trouble.

(4) It is important to examine the subsoil. Very often a large amount of money is wasted in having to build very solid foundations, and many times the site has to be piled.

(5) There must be plenty of room left for extensions.

(6) Due consideration must be given to the capital outlay and cost of the site, for it must be remembered that capital outlay plays a very important part in financial failure or success.

Having selected a site which complies with the above requirements—and it will not be found easy to get one—the next consideration is what sort of buildings should be put thereon, and here comes the question of

The Requirements of an Electric-power House.

Buildings.—Firstly, I will take the case of a power-house where steam engines are to be used, and there will then be the following buildings:—

(1) The main engine-room, which should always be designed large enough for extensions, and this will vary in size according to (*a*) the output of the works; (*b*) the type of plant to be used.

(2) Then adjacent, and usually forming part of the same building, should be the boiler-house, in which are contained

* From a paper by Horace Boot, M.Inst.E.E., A.M.I.Mech.E., Consulting Engineer to the Tunbridge Wells Corporation, presented at the general meeting of the Institution of Municipal Engineers held at the Building Exhibition, Olympia, April 24.

Digitized by Google

the necessary steam generators, together with the automatic coal-handling plant.

(3) Next should come, and usually adjacent to the engine-house, the switchboard arrangements, sometimes placed in the main engine-room, sometimes in a building to itself, with an entrance from the former.

(4) The pump-house, to contain the necessary feed pumps, together with the auxiliary plant, and these should be arranged in such a position that the dust or dirt from the fuel does not interfere with the continuous and satisfactory working of the pumps.

(5) A fuel-storage building, and here care should be taken to prevent the possibility of the fuel catching fire; also the fuel should be stored adjacent to the boilers to avoid excessive handling, because every time the coal has to be handled it usually means an addition to the price of about 3*d.* per ton.

(6) Adjacent should be extensive workshops for undertaking all the necessary repairs.

(7) Stores and storekeeper's office. These should be put into one, and need not necessarily be part of the same building, but they should be near.

(8) Then there are the general offices with accommodation for the staff, consisting of (*a*) the general office for the clerks and consumers; (*b*) the typing-room, with telephones; (*c*) the assistant engineer's office and drawing office; (*d*) the chief engineer's office; all of which should be close to the works.

(9) It is necessary to provide baths and wash-houses for the men in charge.

(10) If batteries are used, then a battery-room, which can be worked into some part of the office building, or adjacent to the engine-room.

(11) In addition to the buildings, provision must be made for the chimney shafts.

(12) The foundations for engines, boilers, pumps, main flues, &c.

In the case of small works it is not necessary to employ an architect, but when it comes to the design of large works it is always advisable for the consulting engineer to employ one. It must always be remembered that the buildings are to house a plant which is going to earn money, and not, as is occasionally the case, a plant which would seem as if it were designed for the buildings. It must also be remembered that in electricity supply works, where the profits are never large, too much money must not be spent on ornamentation nor should palatial buildings be erected.*

It is certainly interesting at this stage to compare the cost of various buildings in electricity supply works to see how the price per kilowatt varies:—

Name of Town.	Total Cost.	Cost of Land and Buildings.	Kilowatts Housed.	Cost of Buildings per Kilowatt.
	£	£		£
Brighton . .	717,738	149,431	5,400	27·67
Glasgow . .	1,368,134	211,172	10,993	19·20
Newcastle . .	1,192,442	169,675	20,000	8·48
Metropolitan . .	1,802,383	435,777	18,500	23·55
Tunbridge Wells .	£1,134	13,207	1,170	11·28
Chichester . .	20,000	600 not land	200	3·0

Construction.—There are so many different methods and forms of construction known now that it is impossible in this short paper to enter into them, but, generally speaking, for small power-houses nothing beats brickwork, with the cantilever roof and lantern lights running along the top.

For very large power-houses concrete and steel construction is the best; that is to say, the whole of the building is constructed of steelwork and filled in with concrete walls. It is important to remember that as little inflammable material as possible must be used in the generating works.

Provided there is sufficient land, it is advisable to build a dwelling-house for the engineers-in-charge and cottages for the principal workmen, so that the men are always near if required.

Water Supply.—In works where steam engines are used it is essential to obtain a good supply of water for the following purposes:—

1. Boiler-feed purposes, in which case it must be fairly pure and soft; if this is impossible, a water-softening plant should be used.
2. Condensing purposes in large quantities.
3. Domestic supply.

Nuisance.—In dealing with the question of nuisance, although the undertaking may be working under Parliamentary powers, it is possible for adjacent owners to obtain an injunction and compel the works to be shut down, and for that reason if it is impossible to get a site away from the residential property, it is advisable to buy up the property first, as afterwards the prices asked may become greatly enhanced.

Type of Plant.

The type of plant makes a very great difference to the size of the works. It used to be the practice to use slow-speed engines; these have been replaced with high-speed engines, taking up much less space, and now in the power-stations the steam turbine is taking the place of the reciprocating engine.

In the relative space required for housing reciprocating engines and steam turbines there is a very big difference in favour of the turbines. The cost of buildings per kilowatt is less, vibration troubles are much less and first cost is low, so that for large works the steam turbine is destined to supplant the reciprocating engine.

Style of Building.—I am afraid power-works do not lend themselves to architectural embellishments:—(1) On account of the capital cost having to be kept down; (2) in that their general shape cannot be very sightly. The buildings, as I have said before, must be fireproof, and the materials used are best left to local conditions. Inside, the walls should be lined to a height of about 10 feet with white glazed bricks and finished off with ornamental chocolate or other bricks. For the cranes the pilasters must be of sufficient strength to carry rails on both sides for the crane, which should lift not less than 10 tons.

Flooring.—The style of the flooring for the engine-room is very difficult to settle, but so far as pattern goes it is hard to beat mosaic or tesselated paving, but it should be set up in squares, as otherwise there will not be sufficient give and it will crack owing to the variations in temperature. In many works tiles are used, but the trouble is that when heavy tools are dropped the tile is usually broken. Hard wood flooring has been tried, but with oil and grease about it is difficult and expensive to keep clean, and when dirty becomes very slippery. For the boiler-house I am in favour of using blue bricks placed sideways on account of their lasting properties.

The design and height of the roof varies according to the plant to be installed. For turbines the height can be kept low; on the other hand, if reciprocating engines are installed, sufficient room must be left below the crane for effecting all the necessary repairs. In all power-works a travelling crane is indispensable.

A site should not be chosen where a great deal of money has to be wasted on levelling, for it is important that the engine-room floor should all be on one level. Again, great care must be taken to see that the flues and economisers are not placed below the ground water-level, as nothing will keep the water out of the flues should this be the case.

It is very difficult to keep the boilers and generators in a line with one another, on account of the boilers requiring so much more room for the same output. In America they often place the boilers on different floors, but this practice has not been copied over here, as there are undoubtedly objections to it.

Refuse Destructors.

Many local authorities consider that the refuse destructor should be situated alongside the electricity works, and that the steam generated by burning the refuse can be used for this purpose. There is no doubt where the loads coincide this can be done with great economy, but where a works has only a lighting load, which does not suit the conditions of burning refuse, the saving obtained by combining the two is not so apparent as it would be in the case of combining a refuse destructor with a waterworks or works requiring a constant amount of power. Anyhow, I venture to think the practice will increase rather than diminish.

The refuse-destructor house should be designed to have an inclined roadway for the carts to deliver above the furnaces, so that they can be charged direct. In the case of destructor buildings it is better to build them apart from the engine-house, to keep the dust out, otherwise trouble will be experienced. One cannot be too careful in building a refuse-de-

* Mr. Boot, in common with many engineers, is evidently under the erroneous impression that architecture, as distinguished from mere building, is principally a matter of money, whereas it is mind rather than money that elevates building to the level of architecture—a fact that American engineers are beginning to realise.—ED.

Digitized by Google

structor house, and it should be well ventilated and arrangements made for cleaning and disinfecting.

Latest Design of Large Power-Works.

Some particulars of one of the latest works—that owned by the London County Council, and known as the "Greenwich Generating Station," for the supply of electric power to the tramways—will be found interesting. The buildings were designed by the Council's architect to the requirements of Mr. J. H. Rider, and trouble was experienced in getting sound foundations, for the whole of the floor has been floated on a concrete raft 6 feet thick, having concrete retaining walls. The buildings are of steel framework enclosed with brick walls having stone dressings for ornamentation. The boiler and engine-houses are faced with ivory-white glazed bricks and a brown glazed dado, which certainly gives a very good finish. The floors throughout are of concrete, covered with terrazzo or granolithic. The boiler-house is 445 feet long by 80 feet wide, and the engine-house is about the same dimensions. Especial care has been taken with the coal-handling plant, and it is capable of unloading no less than 2,000 tons per twenty-four hours.

It is interesting to note here that, although employing water-tube boilers and bituminous coal, very little trouble from smoke is experienced; this is probably due to the fact that the boilers are raised higher than is usual above the fire-bars.

There are many good points in the design of these works that it would be impossible to go into in this paper, but if my readers are interested I cannot do better than refer them to the excellent paper read recently by Mr. J. H. Rider before the Institution of Electrical Engineers.

Buildings for Gas Engines, &c.

Hitherto I have only dealt with buildings required for the generation of electricity when using steam engines, but should gas engines (either suction, producer or power gas) be used, then a boiler-house is not required. Instead of a boiler-house, however, there must be what is known as a gas-house, which should be well ventilated and left open at the sides; space is also required for the gasholders, and it is important to see that the buildings are so designed that all noxious fumes given off by the gas-making or by leaky joints cannot concentrate, but are at once carried away. The engine-house follows much the same lines as that required by steam, except there must be better ventilation, and where this is not always possible forced or mechanical ventilation must be resorted to.

In the works I designed for the city of Chichester, which are, of course, small, but which will probably be followed by all small towns where an electricity supply is not at present given, the buildings only comprise an engine-house. The walls are brickwork, the roof steel framework and slated, the flooring terrazzo, and the generating plant is interesting as one of the first (if not the first) depending upon its supply when employing engines of the Diesel type for prime movers. Here only a simple engine-room is required to house the engines and dynamos, switchboard and other auxiliaries; no boiler or gas-producer house is required. The large storage tank containing the crude petroleum is better placed outside the buildings and need not be covered in.

It will be noticed by referring to the table above that the cost comes out, from the building point of view, very low, which is one of the advantages of using Diesel oil engines for generating electric power.

I am of the opinion that for small towns, where coal is dear, nothing can beat the results obtained by these engines, and what with metallic-filament lamps reducing the cost of electricity to below that of gas (in small towns) and still allowing a margin of profit for the shareholder or municipal authority, there is no reason why many towns now, which hitherto have been too small to put down works, should not follow the example of Chichester.

In designing the buildings it must not be forgotten that no matter what type of plant is used, provision should be made for cableways, pipe trenches, &c.

Lighting, Heating and Fire Apparatus.

The lighting of the buildings will, of course, be electricity, but in generating works it is advisable to provide a second method. For heating the buildings steam radiators can be used where steam is employed. Provision should be made for the usual fire-extinguishing apparatus, both in the engine and boiler-houses, as well as in the offices.

The Wath Urban District Council have instructed Mr. Arnold Hallett, of Sheffield, in conjunction with Mr. H. C. Poole, surveyor, to prepare plans for public baths.

ASPECTS OF APPLIED ÆSTHETICS.—III.

THE last of the three lectures delivered by Mr. James Paterson, A.R.S.A., R.W.S., R.S.W., at the Royal Institution on the above subject was given on May 6. It was entitled "Art and Ethics." We give below a condensed report:—

So little sign of serious purpose is immediately apparent in much of what passes for art in these days that one is not surprised at the tendency, among those who regard life with any gravity, to consider all concern for æsthetic problems as a trifling with the higher interests of mankind. It is said that the faith which enabled the artists of an earlier age to create works showing high moral aim has grown cold, and been replaced by doubts which result in soulless essays in paint, devoid of edification if not absolutely noxious in tendency.

An important section of the British public is not content to take art as a contribution towards a full and joyous life, but demands that it shall be respectable, demonstrably useful, nay actively hortatory in its appeal. Such an attitude would speedily stamp out all vitality in the creative arts. But the great question of art and ethics is one of extreme delicacy and complexity. Excessive emphasis in its treatment is to be deprecated; conventional and long-accepted views demand respectful consideration.

The chief argument of the advocates for a direct moral teaching through art is that since the sense of right and wrong is the main distinction between man and brute, man's highest aim must be to strengthen this sense; unless the arts teach they are not considered to fulfil their function. Such, it is maintained, was the attitude of the sculptors of Greece, of the painters of Italy. But it has been amply proved that this latter persuasion had no foundation in fact; and in so far as they were great artists all other emotions were fused in the enthusiasm of creation, all other considerations subordinated to the mistress art, whom they served.

To bring the question to our own time reference may be made to the late G. F. Watts, one of the noblest of his generation and an artist who will ever be ranked high, if not among the highest. His work acutely raises the point, "How far may art legitimately become a teacher of morals?" His art, moreover, apart from the high aims he publicly enunciated, always furnished material for discussion. His themes appealed to thoughtful minds and engaged the attention of those quite unmoved by normal æsthetic influences. Though much has been written about him, the position he will hold as an artist has yet to be determined.

His career from the first was watched and aided by men of distinction, power and wealth; he was never tempted to curry favour with the multitude. He lived in extreme simplicity and never relaxed his strenuous labour. It was his expressed intention to leave the bulk of his work to the nation, and it became increasingly difficult to induce him to part with any of his pictures. This large and unique collection is permanently housed at Limnerslease, near Guildford. The impression on viewing this memorial of the labours of a truly great man is one of elevation, seriousness and richness. Perhaps it is a little too serious; many of the canvasses are so obviously didactic, though what the teaching may be is sometimes doubtful. The meaning of a work of imagination should dawn upon the spectator almost unawares; a written explanation is something like a confession of incomplete success. In a large number of the works these conditions are fully realised.

Some of the printed criticisms of Watts's work are typical of what passes for art criticism. The writers, though nominally engaged in elucidating the work of the artist under consideration, seem more concerned to demonstrate their own power of word-spinning, clouding their opinion or want of opinion in elusive and fantastic phrases.

It would be futile to approach the work of Watts without sympathy for the masters of paint in the past, and especially the painters of Italy. To anyone whose idea of fine pictorial expression is the more or less accurate rendering of natural objects, the vision of this painter must be vain indeed. Realism had never for him any strong appeal; approximate truth to the visual aspect of things he was not concerned with. Hence the misunderstanding meted out to his works by the general public who throng the galleries. The excellences they are unable to appreciate; the lessons the more didactic pictures endeavour to teach are beyond their ken, and are presented in terms with which they are unfamiliar.

Many of his contemporary artists regard the artist's work with qualified admiration; and history shows that the ultimate position of any artist is similar to that given him

Digitized by Google

by his peers. "Watts," said one famous living painter, "is not one of the great originating minds. His work was from beginning to end derivative, not notably in motive, but in execution. A certain lack of personality marks and mars his technique. Compared with the acknowledged masters of the past Watts never acquired that perfection of touch, that thorough command over his materials which is unmistakable." This is undoubtedly true in part. But it may be suggested that Watts consciously sacrificed such command and touch for the ethical value of his pictures.

Watts declared his intention was "not so much to paint pictures which shall please the eye as to suggest great thoughts, which shall speak to the imagination and the heart and arouse all that is best and noblest in humanity." Undoubtedly high thought and deep feeling may be expressed in terms of paint. But this advocacy of direct ethical teaching appears to traverse Aristotle's definition:—"Art is a free and independent activity of the mind, outside the domain both of religion and politics, having an end distinct from education or moral improvement."

The artistic product must not be judged by the nobility of the subject, but by the clarity, intensity and beauty of its expression. Mr. Watts in many cases mistook the immutable limitations which hedge the artist, and in such examples qualities which make for true greatness are weakened and tend to disappear.

On making acquaintance with any such production we ask ourselves, "Do we like it? Is our imagination touched?" We must further consider if these emotions are created by the work itself. Cultivated people are constantly moved through very trivial and faulty suggestion; the more sacred the association the more liable to abuse. There is great danger that the faculty of judging may become blunted and even distorted through sympathetic acquiescence in what is manifestly poor and faulty.

In architecture, sculpture and painting the higher the artistic appeal, the more limited the response. It is certainly better to enjoy what is open to criticism than to take no pleasure in anything; indeed it is only by the honest exercise of our preference of the best that we can hope to advance in our appreciation and comprehension of beauty; but along with this pleasure received there must ever recur the questioning spirit and a readiness to rise to higher levels of understanding.

A subsidiary point in the contrast between ethical and purely artistic aims is suggested by a practice of Mr. Watts when he had achieved wide recognition. This was the reduplication of certain pictures in response to the demand of those who had come under their sway. Yet for the most part it is entirely impossible for an artist to make a facsimile of a picture, be it his own or another's invention—the vital spirit eludes him.

The advocates of direct ethical teaching usually minimise the less transcendent aims of what they consider mere earthly painters. These they regard as trivial and unsatisfying, permissible perhaps as having some educational value or suited to the passing consideration of frivolous people.

Watts's presentment of his sitters is the antithesis of much of the outstanding portrait-painting of our day, whose brilliant synthesis takes our breath and leaves us convinced doubtless of keenness of vision, but wondering if there were really no human soul beneath the outward mask. Watts seems to have seen almost too much significance in the features before him, and to have wished to remind us of the possibilities which underly them, the experience of life which has made them significant, the hopes that burned in the mind behind the face.

Significance is the commanding feature of one special work of Mr. Watts which it would be invidious not to mention—viz. the colossal "Physical Energy," a replica of which has recently been erected in Kensington Gardens. Here we have a work which, like the picture "Love and Death," possesses such great qualities; criticism regarding details seems an impertinence. Here we have the artist working in the spirit proper to art; he has in no sense allowed his didactic purpose to interfere with the clear and penetrating presentment of an ideal.

"If a picture," says Sir Richard Jebb, "is also a lecture or a sermon, it is so by accident, not in pursuance of the aim proper to art. But this proposition requires to be supplemented by another. Be the subject or the style of art what it may, art must everywhere and always carry with it a certain moral and intellectual suggestiveness, whether the artist intends it or not. Form, colour, light and shade appeal through the sight to the emotional sense of beauty; and this sense is in its turn associated with feelings, thoughts and memories of a subtlety and a complexity which baffle analysis."

The important thing is to enjoy with all our heart what appeals to our own sense of beauty. If, as has been said, no one is entitled to have opinions, nothing can deprive us of our impressions; and by giving these free scope we shall inevitably advance in our appreciation. In the exercise of our faculties of admiration, hope and love there are no limits to growth.

Let appreciation, however, be honest and real, based upon individual perception, not in acquiescence to a general consent. Ready-made opinions are picked up without effort and discarded without regret by the vast majority of people. The relations between art and ethics are of the closest, but they differ both in extent and in degree from those generally understood.

NOTES ON BOOKS.

"The Force of the Wind." By Herbert Chatley, B.Sc. (Engineering). (London: Charles Griffin & Co. 3*s*. net.)

THE impression that one gathers from a perusal of this book is that, in spite of all the experiments that have been made and the theories that have been advanced, our knowledge of the force of the wind is still far from complete. This does not prevent us from recommending this small volume to the attention of architectural students as usefully introducing them to some of the effects that follow from the energy of the wind. It is too much the custom to regard the force of the wind as being simply applied at right angles to any surface it may encounter, and the chapter on the impulsive force of the wind should be carefully studied together with that on the stream line theory. One would then better understand the merits of the ancient fashion of constructing chimney stacks with separated diagonally-placed flues as an approximation to the form of least resistance, a form, by the way, that was the basis of the old ship-builder's theory of "cod's-head and mackerel-tail." Wind does not always strike a surface, say that of a roof, either horizontally or at right angles to the plane of the roof, and the variation in its direction on meeting an opposing surface with the consequent variation of its velocity is of importance as causing the stripping of slates or tiles. This branch of the subject has been studied by yacht designers in connection with the effect of the wind on the sails of racing yachts. Although Mr. Chatley's book does not, as it could not within its limited compass, treat of every aspect of the force of the wind, it will be found very useful as an introduction to the study of the subject.

"City of London Directory." (London: "City Press." 12*s*. 6*d*.)

Works of reference, generally speaking, are published at the very commencement of the year, but the issue of the "City of London Directory"—the 1909 edition has just been published at the offices of the *City Press*, 148-9 Aldersgate Street—is always delayed with intent until the close of April, in order that cognizance may be taken of the numerous civic, municipal and trade changes that may be looked for in the first quarter of the year. Naturally, in a directory dealing with the City of London, especial stress is laid on the institutions connected with the local life of the "one square mile." Firstly, there is a full list of members of the Corporation, arranged alphabetically, and also according to the wards they represent; while, too, the committees are set out, this being a valuable feature to be found in no other annual. The officers of the Corporation are also stated, and the representation of that body on the various governing bodies of London is given. The up-to-dateness of the work is evidenced by the fact that the death of Mr. C. M. Wither, C.C., and the retirement of Mr. C. Val Hunter, C.C., are duly notified. A full list also appears, not only of the members of the London County Council, but of the committees, the "Directory" being the only work of reference that gives this very useful information. The City Companies' section is exceptionally full, the history of each Guild being summarised, the benefits attaching to membership set forth, and the work undertaken in the interests of trade and technical education described. Other features of the "Directory" include portraits and short biographical sketches of the aldermen, the high officers of the Corporation, the members of Parliament for the City, and the masters of City companies; lists of members of the Lieutenancy and Lloyd's; and a map in colours of the City of London.

OUR CONTEMPORARIES FROM OVER-SEAS.

THE *Architectural Record* (New York) for this month devotes its whole space to "fireproof," or fire-resisting houses, including under that category houses built of hollow terra-cotta blocks and of reinforced concrete. Incidentally, the numerous illustrations give us an insight into modern American ways of planning small or moderate-sized detached country houses. Some of the houses have wood floors and roofs, and are only fire-resisting by comparison with the normal frame house.

The *Engineering Record* (New York) commences a description of the central heating and lighting plant for the United States Military Academy at West Point by Mr. Henry C. Meyer, jun. Considerable enlargement of the Academy being in progress and contemplated, the problem of heating and lighting is by no means slight, about 3,000 horse-power with a possible increase of 600 horse-power being required, and the electrical load being about 1,200 kilowatts at present with an additional 200 kilowatts in the future. The detail of this installation is described in the article. An interesting account is given of the reinforced concrete dome to the new Capitol of Porto Rico at San Juan. This dome is double-shelled, and is designed to resist a recorded wind velocity of seventy miles an hour with estimated gusts at ninety miles an hour, and also earthquake tremors.

Correspondence

[The Editor will not be responsible for the opinions expressed by Correspondents.]

Architects Beware!

SIR,—With reference to the letter signed "F.R.I.B.A." which appeared in the November 27, 1908, issue of your journal, it has been brought to my notice that at least one company—the Federal Stone Renovating Company and Mr. Stokes, their chairman—consider my remarks unjustifiable and likely to seriously injure their reputation. That being so, I wish to state unreservedly that I had no intention of casting any damaging reflection upon the financial status of the above company or upon the genuine merits of any particular process or invention.

The sole object of my letter was to warn my brother-architects, especially the less-seasoned ones, against the danger of being taken at an unguarded moment and expressing opinions which might afterwards hold them up to ridicule. That this view was accepted by at least one other architect was shown by the letter which appeared the following week and signed "Another F.R.I.B.A."

I can only repeat that I am very sorry, and trust those who consider themselves aggrieved will be charitable enough to accept this withdrawal in all sincerity.—I am, Sir, yours faithfully, F.R.I.B.A.

Designing a Steel Box Girder.

SIR,—My attention has just been called to a letter signed J. Myrtle Smith, A.R.I.B.A., in your issue for May 7, asserting that the design given by me in a paper read before the Association of Engineers in Charge is impossible of execution, and expressing surprise that this was not noticed by any of the engineers to whom the lecture was delivered. Why it should be impossible is not stated, but the idea appears to be that there is insufficient room for the "holder-up" to get inside to hold the rivet heads while the rivetting of the inner angles is done on the outside. The space inside the girder is 15 inches wide (14¼ inches net) by 28 inches high, which is more than enough, as I have before me the drawing of a box girder of similar construction, designed by me fifteen years ago, in which the inside space is 12⅛ inches wide by 22 inches high, and no difficulty was experienced during the construction in putting in any of the rivets.—Yours faithfully, HENRY ADAMS, M.Inst.C.E.

The Building Exhibition.

SIR,—I quite agree with your several correspondents. Yes; the exhibit of drawings was missed. Provided you had been able to exhibit in a better position, I consider the collection was quite as good as many a Royal Academy (Architectural Room) Exhibition.—Yours faithfully,

A COUNTRY EXHIBITOR.

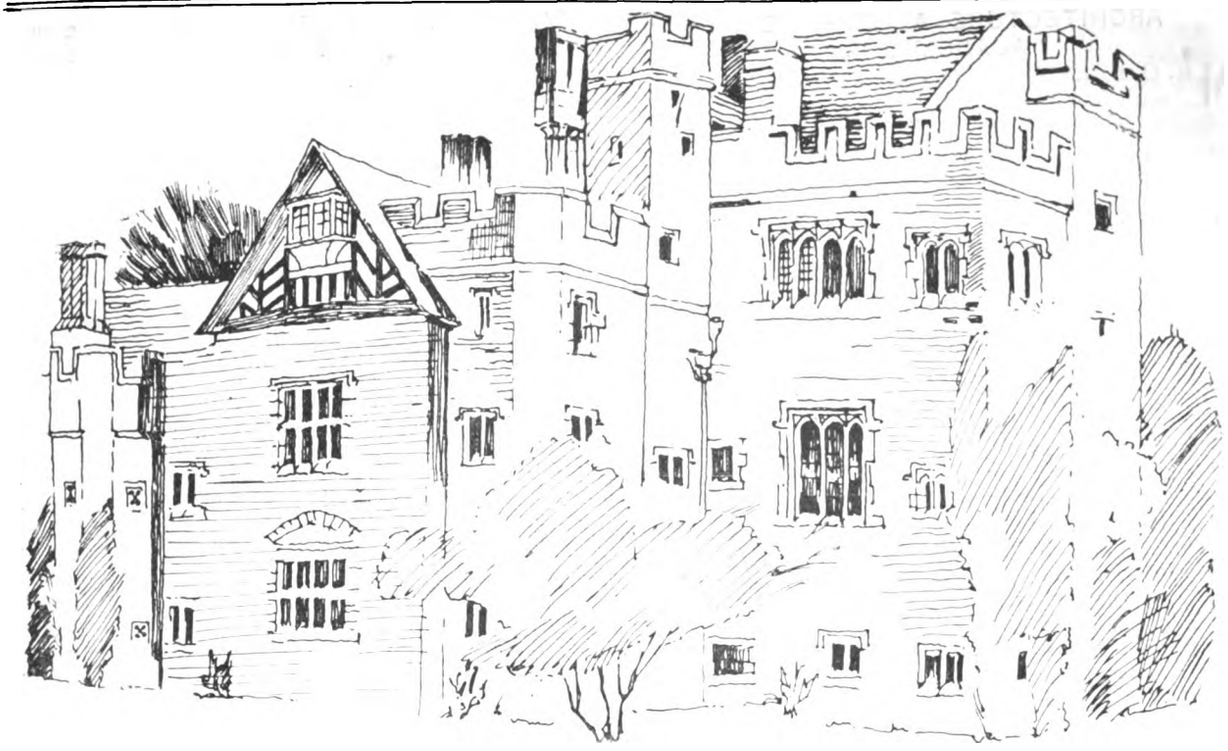
GENERAL.

Mr. J. S. Gibson, F.R.I.B.A., has been appointed assessor for the Middlesbrough public library competition on the nomination of Mr. Ernest George, P.R.I.B.A. It is understood there are from 150 to 200 sets of plans to adjudicate upon.

When the Master and Companions of St. George's Guild, Sheffield, hold their meeting at Ruskin Museum on May 21, the Lord Mayor and Alderman Nuttall, on behalf of the Corporation, will present a proposal to renew the twenty years' lease of the collection in the Ruskin Museum, which expires in 1910, for a further term of twenty years, and will offer to maintain the museum at Meersbrook Park for that period on the conditions of the existing lease.

Hamilton School Board had under consideration last week a communication from the Institute of Architects, Glasgow, stating that if the Board did not give fuller effect to the recommendations of the Institute they would be under the necessity of advising their members not to take part in the competition in connection with the plans for the new academy, which is to cost about 30,000*l*. The Board agreed to give effect to the recommendations in so far as giving the Institute the assurance that a professional man of standing would be appointed as assessor to adjudicate upon the plans and fixing at once the fees of the architect, but the Board declined to publish the name of the assessor until the competitive plans of the new building were in their hands. The architect's fees were fixed at 3½ per cent.

The Manchester Society of Architects at their annual meeting last week elected the following office-holders for the coming year:—President, Mr. P. S. Worthington, M.A., F.R.I.B.A.; vice-presidents, Mr. W. C. Hardisty, F.R.I.B.A., and Mr. Edgar Wood, A.R.I.B.A.; honorary secretary, Mr. Isaac Taylor, F.R.I.B.A.; assistant honorary secretary, Mr. Gerald Sanville, A.R.I.B.A.; members of Council, Messrs. John Brooke, Godfrey Colles, A. E. Corbett, John Ely, J. T. Halliday, F. E. L. Harris, P. D. Lodge, F. W. Mee, Paul Ogden, J. H. Sellers, John Swarbrick, and J. H. Woodhouse. The membership of the society stands at 265.



At the Annual Vestry Meeting of the cathedral church of St. Philip, Birmingham, the Rector said with reference to the cathedral tower that they had had it examined by a very competent architect, who said that though the substructure was quite sound, the outer casing was gradually wearing away, and that something must be done in the way of restoration or replacement. It was to be hoped that before the summer was out they would be able to remove the unsightly structure placed for protection's sake against the west front of the cathedral.

The Sheffield City Council organised a competition for laying out the Rivelin Road Estate. The competition was confined to architects practising within a radius of thirty miles of Sheffield. Eleven designs were sent in. The first premium of twenty guineas has been won by Messrs. J. Creswick Brameld & Sons, of York Street, and the second, of ten guineas, by Mr. James Miller, A.R.I.B.A., of Smalldale, Bradwell.

The Borough Surveyor to the St. Marylebone Borough Council recently complained as to the great inconvenience he experiences in not being able to take prompt proceedings against persons who begin to take down buildings in the borough, within 10 feet of any highway, without first giving notice to the Council of their intention to do so and obtaining a licence for a proper hoarding. Having regard to the special nature of these cases and to the need for prompt action, the committee recommended that the borough surveyor (after consultation with the town clerk) be authorised to take proceedings without giving the notices required by the Statutes, Metropolis Management Act, 1855, and London County Council (General Powers) Act, 1890.

The Report of the Liverpool city building surveyor (Mr. John T. Alexander) on the work of his department during the year 1908, states that the number of houses erected during the year was 1,850, or 183 below the average for the previous twelve years. There had been a marked reduction in the number of houses at a rental of less than 7*s*. a week, but more of the common six-room type of houses, commanding rentals of from 7*s*. to 9*s*. 6*d*. a week, had been built, while no houses of a high rental had been erected within the city boundaries, with the solitary exception of a single house at Aigburth. In the Walton district, owing perhaps to increased railway facilities and comparatively lower rentals, there was a marked increase in the number of houses built. The estimated number of houses in the city was now 151,697.

A CORNER OF COMPTON WYNYATES, WARWICKSHIRE.
From a Sketch by BANISTER FLETCHER.

THE WEEK.

THE opinions expressed by Mr. A. B. HOWES, barrister-at-law, in his paper recently read at the Surveyors' Institution, and entitled "Quantity Surveyors: a Review of their Legal Position," if correct, considerably modify the impression held by most quantity surveyors. It has usually been considered that a quantity surveyor was liable to the builder for any shortage in the quantities, but Mr. HOWES put it that, as there is no privity of contract, the quantity surveyor is not liable to the builder for negligence in preparing quantities, but only for fraud or misrepresentation. As in the hurried conditions under which quantities are usually prepared it sometimes happens that mistakes are made and quantities are "short," many of the best firms of surveyors have been called upon by builders for recoupment, and have accepted the liability without demur. On the other hand, Mr. HOWES said that between owner and quantity surveyor there is a contract of service, and hence a warranty of reasonable if not absolute accuracy. The architect's position, according to Mr. HOWES, is that he is under no liability to either the builder or the surveyor in respect of quantities. The owner is liable to the surveyor for payment until the acceptance of the builder's tender, and after that the builder is liable.

THE Italians, although they will allow no foreigners to excavate in Italy, even when, as at Herculaneum, they cannot find the funds to do the work themselves, have nevertheless made arrangements for the maintenance of an Italian Archæological School at Athens, one object of which will be to undertake excavations. We imagine the Italian Government will be in somewhat of a dilemma if the Greeks, as they quite naturally might, were to ask for permission to excavate on the site of the Dorian settlements in Sicily or Magna Græcia.

THE persistency and influence of those who desire the maintenance as a complete entity of the Indian Collection at South Kensington appear likely to be successful, as the sympathy of Mr. RUNCIMAN, President of the Board of Education, has been won to this view. The probability therefore is that we shall have the India Museum in a new home. Certainly, for the sake of the collection, it would be better even that it should be housed in the extended Victoria and Albert Museum, than in the mean and unsafe shanties in which it is now located.

THE difficulty nowadays of obtaining really good "soft wood" timber was illustrated by the evidence and judgment given in the case at the Salford County Court of WARD & GOLDSTONE *v.* G. N. HADEN & SONS. The plaintiffs agreed to supply a certain quantity of red wood casing for electrical wires which was to be free of all knots "and other defects." Some of the material supplied was admittedly sap-wood, and defendants objected to pay on this account, but the Judge decided that sap in wood was not a defect, and that the red wood supplied was of average quality. He therefore gave judgment for the plaintiffs for the amount claimed.

THE gift of 50,000*l.* by the Goldsmiths' Company to the Imperial College of Science and Technology, South Kensington, should provide that institution with one of the best equipments for teaching engineering to be found in England, a thing in which London has been hitherto lacking. The objects of a central college such as the one at South Kensington, which is professedly intended for the training of teachers in technical schools, should embrace research as well as instruction. Certainly it is not for want of material provision that technical instruction in this country is far inferior to what it ought to be and to what it is in Germany.

SIR WILLIAM RICHMOND has written to the *Times* protesting, on behalf of the Society for the Protection of Ancient Buildings, against the "restoration" or renewal of the niche and canopy work of the west front of Exeter Cathedral. The Society states that the old niche work was of the finest white stone, admirably sculptured, and with expressions of delicacy and finish that claim for the work the highest place in mediæval craftsmanship," and Sir WILLIAM RICHMOND complains that a coarse yellow stone has been substituted. The Society often makes mistakes, and would seem to prefer that the "finest white stone," probably Caen stone, should be left to moulder and decay until nothing but a powerful effort of the imagination could restore for us a presentment of what the old work really looked like.

ARCHITECTURE AT THE ROYAL ACADEMY.—II.

MR. O. BEESTON HATCHARD'S "Proposed Garrison Church, Khartoum," is shown in a brilliantly coloured perspective that well conveys the idea of the blazing sunlight under which the building will be seen. The design appears quite suitable for the locality, in which anything like elaborate detail would be practically impossible, and the author has skilfully obtained good architectural effect by the use of the simplest forms. Red brick, white stone, rough-cast (in moderation) and tile roofs are the materials. Shade is obtained by means of verandahs and wide projecting eaves. The "New Chancel, St. Mary's Church, Snettisham," by Messrs. Ravenscroft, Son & Morris, is unaffected and harmonises perfectly with the Decorated work of this well-known and beautiful church. Mr. R. Weir Schultz's "Cathedral Church of All Saints, Khartoum," of which both the interior and exterior are shown, apparently is an attempt to obtain the shade necessary under tropical conditions by a double wall plane, the external with triangular-headed Romanesque window openings, and the inner with pointed arches enclosing tracery of some kind not clearly indicated. The nave is spanned by pointed arches in red brick and stone. Considerations of expense have clearly limited the scope of the designer's ideas. Another design for a church in a sunlit country is "A Church near Capetown, S.A.," by Mr. Walter H. Jaggard, in which smallness of window openings is relied upon to prevent undue glare of light; by leaving the walls white in the drawing an idea of bright sunshine is conveyed. Mr. Edward Warren's "Triptych for a College Chapel" is a pleasant conception without elaborate architectural ornament, relying for its effect upon the figure paintings framed in green and gold. The body of the triptych shows angels adoring the Crucified One in the centre, and the wings the twelve Apostles also in adoration. "St. Barnabas Church Hall, Gorringe Park, Surrey," by Mr. Burke Downing, is a nice coloured drawing, which was reproduced by us in our issue of July 10 last year, and shows a clever and comparatively inexpensive design for a mission building, in which good architectural effect is obtained by the expenditure of brains rather than money. Mr. Roland W. Paul's "Pembridge Church, Herefordshire: Interior after Restoration," is a good pen-and-ink perspective from which it is difficult to gather how much is old and how much new, save that there can be no doubt the latter includes the open screen and hanging cross. "Buckfast Abbey Church," by Mr. Fredk. A. Walters, appears quite a cathedral in size and dignity. The style adopted is that of the English Transitional period, and shows once more how a great architectural conception may be independent of elaborate detail. A lofty central tower and a chapel of six altars at the extreme east end on the lines of Durham's chapel of the nine altars are striking features of the plan, to which may be added the position of the choir west of the transeptal crossing. Professor Beresford Pite, by his "Extension of Frinton Church, Essex," is going to change a commonplace little building into one highly picturesque and yet not too grand to retain the character of a country church. The picturesqueness is largely due to a well-designed wooden bell turret which one might describe as a glorified sance-bell cote. Plaster and red brick give brightness of colour, and good tracery of Perpendicular type interest to the design. The "Third Church of Christ Scientist," by Messrs. Fair & Myer, is a remarkable design, which is not wholly shown, but sufficiently suggested by a good coloured perspective to enable us to grasp that its salient features are quite out of the common. The entrance front has a tall, square tower set in the crown of a semicircular recess between two square blocks, and behind the tower is a low dome that presumably covers the body of the church. The drawing shows a polychromatic use of material that ought to delight the heart of Sir William Richmond. "New Church of St. Michael, Sunnyside, Berkhamstead," by Mr. Philip M. Johnston, is a quiet country church with a big tiled roof coming down low over nave and aisle, and with a square-tiled bell-cot at the west end. Mr. J. Coates Carter's "The Gate House, Anglican Benedictine Monastery, Caldey," is a powerful piece of design in rough masonry and simple detail, quite expressive of the purport of the building of which it forms a part. Mr. Matthew Honan's "New Church, Warrington," is shown both by interior and exterior views, and is broadly treated with a distinctly Italian feeling in the composition and a reminiscence of Romanesque work. The interior would afford a fine field for colour decoration, and would seem to have been designed with this intention. "New Unitarian Church, Lewisham," by Messrs. E. L. Wratten & W. H. Godfrey, is a simply treated mission-hall type of church with plain semicircular arches. Mr. J. Ernest Franck's "Church Hall for St. Mary's, Spring Grove," is a mission hall simply treated in brick with an elaborately detailed stone porch that provides the excuse for some more trenchant design. Sir Charles A. Nicholson's "Design for Rebuilding Clifton College Chapel" has for its chief feature, in the internal view that is shown, a vaulted crossing with a lantern, which reminds us in a way of the central feature of Ely. Coloured decoration in the form of paintings in architectural panels is indicated. Mr. W. Talbot Brown's "Church of St. Peter, Rushden," has breadth and dignity, and is a fitting design for a town church in brick without extravagance. Tile roofs, a small bell tower, gabled vestry and Perpendicular tracery help to make up the character of the design. In his "New Church, Wellingborough: Exterior," Mr. Arnold H. Hoole seems to have determined not to show his roofs, which, if the lines of the eastern gable are true, are of flat pitch and certainly have high parapets. It looks rather curious to see the tower only a little higher than the roof parapets.

ARCHITECTURE: ITS TRUE PRINCIPLES.—X.

By R. OWEN ALLSOP.

The Symmetrical and Asymmetrical Plan.

THE objection to the absolutely symmetrical plan is that it always suggests that the requirements of practical service have suffered in order to render the plan symmetrical. That this is often actually so we know well; that it is invariably so we have good reason to surmise.

The advocates of the symmetrical plan urge that the making of such is difficult, whereas the making of a plan by piecing together, anyhow, the several component parts, is an easy matter. The mistake here made seems to be to confound genuine thoughtless patchwork with scientific asymmetrical planning. It can be shown that the *striving* after symmetry of plan must necessarily entail a sacrifice to practical needs.

It seems much to say that there is something positively offensive to the eye in the perfectly symmetrical building—that of absolute symmetry both as to front and sides. This must be more mental than an appreciation of the eye, for we have already considered that the effect of symmetry, especially in large buildings, is quite lost in perspective. The sentiment then must arise from a mental consideration that the symmetry is forced and against truth and sincerity of purpose, in that the practical needs of the building must suffer. In claiming, then, that the symmetrical plan is good, because more difficult to make, the advocates of the system are standing upon ground not quite secure. May there not be a still more excellent system of planning? And is the statement that the symmetrical plan is more difficult to make quite true—is it at all founded on truth?

To give effect, whether architectural or otherwise, by symmetry is the easiest thing possible. The child writes a name and doubles the paper whilst it is yet wet, and is pleased with the symmetrical smudge resulting. The turner in a marvellously short time produces a symmetrical baluster from a shapeless mass of wood. Truly the mere production of symmetry calls for little or no science, skill or art; the making of a balanced effect does, however, necessitate the highest artistic knowledge and skill.

The symmetrical plan supposes that the practical

Digitized by Google

requirements are just exactly duplicated—even the one side and the other. This necessarily supposes that there are such conditions that the most practically convenient disposition is one-half on the right, and one-half on the left-hand side. Can we possibly conceive of such conditions in nine out of the ten buildings needed either for the service and convenience of man, or to the honour and glory of GOD? Who would wish (to produce symmetry) for two further campaniles at St. Paul's Cathedral? Who would prefer two added eastern towers to our asymmetrical cathedrals? There is no disputing as to taste, but to some of us the perfectly symmetrical building of multifarious practical needs—as in civil architecture—is offensive. We have already suggested the reason—the sacrifice of truth and sincerity to produce that which is the mere essential characteristic of the beauty of vase or monument. The latter—if a work of architecture at all—is ordinarily a very low order of such.

What then must be the main guiding principle of planning? What, surely, but honesty of purpose? And how is this principle evidenced by the production of a plan whose motive is not practical service but the production of the beauty that characterises the inanimate crystal in its formation? The perfectly symmetrical building always suggests green cloth and a glass case—the cardboard model. Here, the eye, embracing the whole of a large building at one glance, can appreciate the symmetry. The conditions are different where we regard a large building in the actuality. On the other hand, extreme asymmetry—as in fig. 23—suggests anarchy.

The great error into which the extreme symmetrists fall is plainly in ignoring the fact that there are three main styles of planning:—(1) The perfectly symmetrical, (2) the patchwork, and (3) the honest and scientific.

Under the first principle of planning, if our practical needs produce naturally that which has not (in spite of some effort) the symmetry of halves, we force on such

FIG. 23.—AT PONTRESINA.

symmetry unnaturally. Practical convenience suffers in consequence. The *plan is bad*. By the second "principle," being too lazy or ignorant to do otherwise we patch on part to part wholly irrespective both of convenience and effect. The plan is worse. On the scientific system—hence the artistic system—we throw our utmost energies into producing the utmost convenience with the utmost effect, but we do not sacrifice practical needs to that which (it is supposed) will give a pleasing effect to the eye. Which is the better system of planning?

What is wrong with the horse, that he has not either a tail or a head at both ends? Surely nature has been wrong (according to the extreme symmetrist) in not thus balancing the appearance! To our way of thinking we can by analogy learn much from such a consideration of natural animal forms. The animal has a head—a principal part—a dominant. So in building there are principal parts. But in the building of perfect symmetry the whole is subordinated to an imaginary axis—for to such we must at last refer all symmetry of halves.

Now it is evident that the architect who produces a perfectly symmetrical monument or crystal-like plan has chiefly kept his attention fixed upon the symmetry. The practical needs have been wholly secondary—indeed, of importance of an infinitely lower grade, being in fact absolutely sacrificed and ignored.

This as a proposition may at first be denied; more careful consideration will show that the statement is not over exaggerated—not, in fact, exaggerated at all. The aim is the symmetry of halves. It is not the plan as a practical working device for the benefit of those who are to be installed on the building or to have approach or access to, or thoroughfare therein.

The same object is before the designer in producing

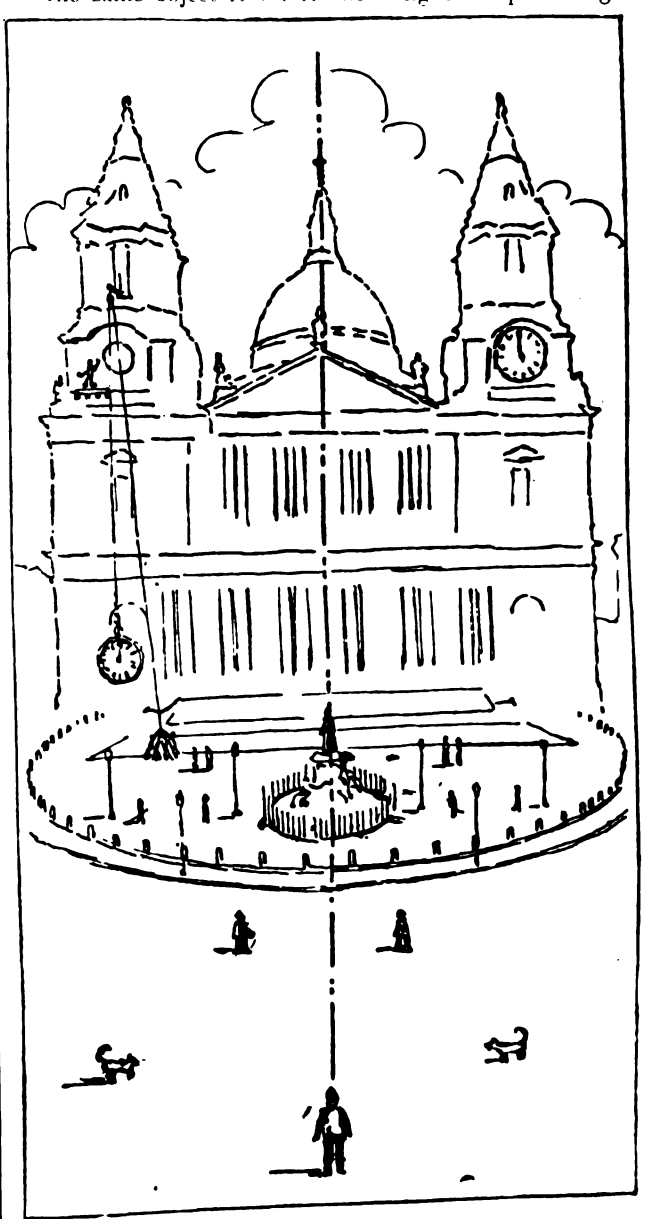

FIG. 24.—WEST FRONT, ST. PAUL'S.

a genuine monument, or a vase, or other minor class of ornamental composition in three dimensions—a solid.

The necessity for exact symmetry is frequently referable to the practical demands of stable equilibrium. This principle concerns vertical division only. The governing factor in this case is, therefore, either a perpendicular axis or plane, and in any case the whole refers to the earth's centre. An ordinary stone column may be instanced. We are, therefore, at times justified in ultimately referring the principle of exact symmetry to the overruling force of gravity. We should see at once the absurdity of an idea of dividing a 50-feet high building

Digitized by Google

by a centre horizontal line 25 feet from the ground level, and then making the part above and below "symmetrical"—the same above and below and referring to the centre horizontal line.

The most important practical fact concerning exact symmetry is that in this arrangement every part of the whole is subordinated to the effect of symmetry. The great power of exact, mathematical symmetry is thus at once evident; and at the same time its unnaturalness—where this narrow oneness of effect is not demanded—is also made clear. In the case of a bowl of flowers, if we assume that we have a certain number either all alike or of different variety, no one with natural good taste would proceed to arrange these in the bowl or vase in perfect "symmetry." Were this done, the attention would be called off the flowers themselves and directed to a *pattern*, as such. All their individual beauty would be prostituted to this pattern. If we are designing a doorway, the complete portal is the theme, to which all parts must be subordinated. The end and aim here differs, and absolute equilateral symmetry the principle justly employed, at any rate in the main mass. It is, by these considerations, evidently suggested that there is on the one hand absolute, rigid symmetry, and, on the other, harmonious grouping; which is a reflection simply bringing us, by another road, to symmetry and balance as separate things.

We may make a floral cross or anchor, but that is a different thing from making a pattern of flowers of a varied outline repeating on either side of a neutral axis; for in the former case we decorate (embellish) the cross or anchor, and to these simple forms the flowers are subordinate ornaments or enrichments. It is another thing to construct an ornament of flowers so that the flowers are subordinate to a (*per se*) senseless form. For the practical purposes of the architectural designer it suffices for him to remember that exact equal-halved symmetry makes for one, absolute and only, while harmonious grouping, or balance, ensures unity without submerging individual component parts; and we can always powerfully aggrandise the part of asymmetrical placing with respect to the whole.

There is a favourite (or common) photographic view of St. Paul's Cathedral showing the west front with the dome and cross exactly central. The complete picture constitutes a *pattern*, and the pattern dominates the whole. If this pattern-like appearance is so desirable we have, in our rough sketch, endeavoured to enhance the effect by some additions, made and in the making.

(*To be continued.*)

THE IRON AND STEEL INSTITUTE.

THE fortieth annual general meeting of the Iron and Steel Institute was opened on May 13 in the hall of the Institution of Civil Engineers, Sir Hugh Bell, Bart., President, in the chair.

The report of the Council for 1908 stated that the year had been one of considerable activity and progress. The number of ordinary members had increased by 116, and the total number of members on the roll on December 31 was 2,128, as against 1,522 in 1898. Severe losses through death had been experienced during 1908, the list comprising forty-one names. The statement of accounts showed that the receipts for the year amounted to 6,367*l.*, and the expenditure to 6,011*l.* The Council announced the grant, by the Royal College of Heralds, of armorial bearings to be borne by the Institute, the gift of the President, Sir Hugh Bell, Bart. Mr. George C. Lloyd has been appointed to succeed the late Mr. Bennet H. Brough, who died in October.

Owing to the steady growth of the membership of the Iron and Steel Institute, and to the expansion of the Institute Library, the Council decided, early in the year, to secure more commodious offices, and to effect certain improvements in the internal arrangements. Negotiations were therefore opened with the Westminster Trust, who are the landlords of the premises, and the Council concluded an agreement in February. The new premises consist of a suite of ten rooms, on the first floor of No. 28 Victoria Street, having precisely the same outlook as the recently vacated offices, and access being obtained from the same main entrance and staircase. The Council have also obtained the use of a storeroom, conveniently situated in the same building, on the sixth floor.

The new by-laws were proposed and unanimously adopted by the members.

Among the papers read at the opening meeting was the following by Mr. J. Cruickshank Smith, B.Sc., F.C.S. (London), on

The Value of Physical Tests in the Selection and Testing of Protective Coatings for Iron and Steel.

The expression "protective coating" is now applied to any material or mixture of materials—whether oil, varnish, paint, or enamel—employed with the specific object of protecting a structure from external influences.

There is a growing tendency to regard such materials as coming within the scope of engineering materials or materials of construction. Little argument is necessary to prove the correctness of this; it is self-evident that the engineer who designs and selects the materials for the structure itself should also select the final coating on which, in a large measure, the life of the structure depends.

There has been a noteworthy increase during recent years in the attention devoted by technical chemists and testing engineers to the physical and mechanical properties of paints, varnishes and other protective materials. This is largely due to the growing appreciation of the fact that in actual service and under the conditions of prolonged exposure to the atmosphere, moisture, &c., the durability or life of protective coatings depends as much on physical laws as on chemical ones, and further, that the physical state or condition of a protective coating has an important bearing on its liability to chemical influences both external and internal. In other words, it is not always composition that determines the technical value of an article. Other factors besides composition enter into the question, and it is the determination, and if need be the measurement, of these factors which the author would include in the expression "testing."

This is neither the time nor the place to enter into a voluminous discussion on all the moot points which arise in connection with the selection and application of protective coatings. The author's object at present is to indicate the trend of technical opinion in regard to the principles to be followed in the testing and technical valuation of such materials prior to exposure under average or normal conditions, and to point out how the engineer who is responsible for the selection and application of protective coatings can best safeguard the interests of his client, the owner of the property under treatment.

The chemical aspect of the question will therefore be left on one side, and those physical and mechanical tests which recent experience has proved to be most valuable in enabling one to arrive at a judgment as to the comparative merits of different protective paints will be dealt with briefly.

Protective coatings consist as a rule of a pigmentary portion and a fluid medium or vehicle. The author desires to point out in passing that pigments are themselves invariably defined and valued in terms of physical properties—opacity, insolubility and degree of crystalline structure; also that the fluid vehicle after drying presents certain mechanical features as to elasticity, hardness and the like, which determine its value as a paint material. If it be borne in mind that a film of protective paint spread over a continuous length of iron or steel surface seldom has a thickness of more than $\frac{1}{2000}$th of an inch, and that the life, or at any rate the cost of maintenance, of the structure depends on the capacity of the paint film to expand and contract, without breaking, in accordance with the expansion and contraction of the structure itself, to maintain a hard and impervious surface, to resist the solvent action of rain-water and chemical impurities in the atmosphere, it will, the author assumes, be granted that the physical properties of paint films are of pre-eminent importance in determining the selection of the materials which yield the said films.

The physical tests which may be employed as a guide in selecting protective coatings are of two kinds:—

(1) Those applicable to the paint itself.

(2) Those applicable to the film produced by the drying of the paint.

The more important of these tests will now be discussed very briefly, and the author would point out that he refers here only to tests which experience has proved to be of real utility in solving the problems connected with the subject.

Digitized by Google

1. *Tests Applicable to the Paint.*

(a) The Pigment and Vehicle should be properly proportioned in order to insure efficient Application and the Minimum of Free Oil Space in the Dry Film.—The physical property which underlies the question of correct consistency of the paint is that of "viscosity," and on the viscosity of the paint depends to a great extent the efficiency with which it can be applied. If the viscosity be too high, the paint film will be too thick, and imperfect and unequal drying will probably result. If the viscosity be too low, the paint film will probably be too thin, and will tend to run down in tears. Unfortunately no cut-and-dried method has yet been elaborated by means of which the correct consistency of a protective coating can be accurately determined before use. This is, therefore, a point which the user of protective coatings must perforce leave to the producer of these materials, although it is within the power of the consumer to protect himself by specifying that the consistency or viscosity of the paint shall be such as to enable a film of a given thickness to be produced under stated conditions.

The question of free oil space in a paint film is an extremely important one, and it has been proved that the smaller the amount of free oil space the more impervious to moisture and as a rule the more durable will the film be, the currently accepted view at present being that the fluid medium or vehicle in protective coatings acts merely as the elastic binding or cementing medium which holds the real protective agent—namely, the pigment—together. By examining the films produced by different paints under the microscope one can obtain most useful information as to the relative areas occupied by solid pigment and transparent vehicle, and in selecting a protective paint careful examination under the microscope should never be neglected.

(b) The Size of the Pigmentary Particles should be Small and Uniform.—This is now accepted by paint experts as a proved truth, and the author might refer in passing to the now classic research, which finally set this matter at rest, conducted some years ago by Mr. Robert Job, chief testing chemist to the Philadelphia and Reading Railroad.* The actual measurement of small pigmentary particles is a matter requiring some experience and manipulative skill, but such measurements cannot be neglected in the physical testing of protective coatings. Without entering into unnecessary details, it may be said that the pigment in a paint may be considered to be finely ground when the largest particles do not exceed .001 inch in diameter. In the case of a paint which proved after exposure under service conditions to be a thoroughly satisfactory protective coating, the largest particles were of this diameter, and there were very few of that size. The smallest observed particles had a diameter of .0002 inch, and the estimated average diameter of all the particles was .0004 inch. In the case of another paint which proved unsatisfactory in service and whose composition was practically identical with the paint just referred to, the largest particles were .018 inch in diameter, and there were many of .010 inch, while the finest particles had a mean diameter of .0002 inch, the estimated average size of all the particles being .008 inch.

Here again the requisite physical state of the paint can be secured by suitable specification.

(c) The Pigment and the Vehicle should possess the Minimum Tendency to Separate from each other.—Theoretically a protective coating consisting of pigment and vehicle should be in such a state that it flows like a homogeneous liquid without separation into its component parts. It is within the power of manufacturers of these materials to approximate to this theoretical state of things under reasonable conditions, and a very simple physical test can be applied in order to determine whether separation will occur. This test was devised by Job in connection with the investigation referred to above, and after considerable personal experience of it the author can confirm its value. The paint, in a condition ready for use, is placed on a piece of sheet glass, which is then stood vertically for one hour at a temperature of 100° F. No separation of the pigment and vehicle should be observable at the end of that time. To make the test more severe the paint may be thinned with raw linseed oil, and even then no palpable separation ought to occur.

(d) Accelerated Tests.—Obviously the main purpose of tests such as those that have been described is to enable one to arrive at a judgment as to whether the material under test is likely to behave satisfactorily under service conditions. In order to determine this with perfect accuracy a whole series of long and laborious exposure tests would have to be applied. This under ordinary commercial conditions is not possible, therefore attempts have been made to arrive at satisfactory conclusions by exposing the paints to severe conditions for a short space of time, and by examining the films so produced in order to see whether they are free from the defects which one would expect to find in them after long exposure under milder conditions. This method has been applied with considerable success in the technical valuation of oil varnishes for protective purposes,* and is likely to be employed more widely in the future.

2. *Tests Applicable to the Film.*

(a) Determination of the Thickness and Uniformity of the Film.—Although the average thickness of a paint film extending over a considerable surface may be $\frac{1}{1000}$th, or $\frac{1}{500}$th, or $\frac{1}{200}$th of an inch, the thickness at various points usually varies within considerable limits, and obviously the actual utility of the film will depend greatly upon the thickness at the thinnest point. It is therefore of importance to determine whether the film produced by a given protective coating is liable to produce an uneven film. The average thickness of the film can be readily determined by applying a coat of the paint on a piece of perfectly plane glass, and when dry covering it with another piece of similar glass. The thickness of the two pieces of glass plus the film of paint can then be determined by the calipers, and if from the figure so arrived at the thickness of the two pieces of glass by themselves be deducted, the mean thickness of the paint film is obtained. It is not so easy to determine the actual variation in the thickness of the film at different points, but useful information in this respect is yielded by examination under the microscope. It is evident that inequalities in the thickness of the film are largely due to variations in the size of the pigmentary particles. Consequently if the latter factor is properly adjusted there will be comparatively little danger of the film exhibiting inequalities.

(b) Strength of Film as Determined by Breaking-machine.—It is only within the last twelve or eighteen months that actual measurements have been made of the strength of a paint film, and an ingenious instrument has been devised by Mr. R. S. Perry for this purpose. It is called the "Filmometer," and is shown on a diagram which the author has had prepared. Although figures have been arrived at indicating the pressure required to rupture various paint films of known thickness, the tests are hardly far enough advanced yet to enable one to predict with perfect certainty from the figures obtained what relation obtains between them and durability in service. All that can be said at the moment is that much valuable information concerning the effect of age upon a paint film as influencing its strength and elasticity may be expected in due time. As Mr. Perry points out, these are two vital qualities in a paint, as it is through them that a paint resists abrasion, cracking, peeling and blistering.

(c) Elasticity of Film.—This factor also can be measured by the filmometer, and the remarks made under (*b*) apply here with equal force. It is hoped that during the next twelve months sufficient data will have been accumulated to enable the filmometer to be made use of in testing paint films for technical purposes.

(d) Permeability of Films by Vapours and Gases.—It has been abundantly proved that every paint film hitherto obtained is permeable by moisture. Whether this moisture finds its way through the film through pores or whether it percolates by a process of osmosis is a moot point; nevertheless the fact is proved that paint films are permeable by moisture and gases. They differ, however, in the degree of permeability, and the less pervious they are the better will they effect their purpose of protection. A method for determining the relative permeability of paint films has been devised by the Scientific Section of the Paint Manufacturers' Association of the United States and is indicated on the diagram.

(e) Hardness of Surface of Film.—Many protective coatings have to resist surface blows, abrasions and the like. Hardness, therefore, is an important factor. It can be measured in terms of a definite standard by means of the instrument devised by Bailie and Laurie,† of which the author has a specimen here.

The various problems in connection with the physical and mechanical testing of paint films and protective coatings, and the connection between the results of these tests and

* *Journal of the Franklin Institute*, July 1904.

urability under service conditions (which is the true riterion of the value of protective coatings) are being arnestly investigated at the present time, and it is probable hat much valuable information will be available before long.

In conclusion the author would like to direct attention to vo aspects of this important subject which are liable to be st sight of. One is the need for carefully drawn specifica-ons, worded in such a manner as will enable the consumer o obtain the full advantage of the most recent scientific esearch in the domain of protective coatings. The second the all-important position of the consumer in such matters. fter all it is the owner of the property that is the con-umer, acting through his professional adviser the engineer, ho is primarily interested in obtaining the best value he an for his money. But in order to do this the consumer ust be able to state intelligently what he wants and to ssure himself that he gets it. The author cannot do better n this connection than quote a few sentences which formed art of Dr. C. B. Dudley's presidential address some years go to the American Society for Testing Materials. He aid:—"The influence and voice of the consumer in the anufacture of commercial products has come to stay, and it s simply the part of wisdom for all concerned to recognise he situation. Also, since both the producer and the con-umer have a direct interest in the product or thing made, he one in its production and sale, the other in its use, there s no real reason why each should not study the product in ost minute detail. If the producer knows better than the onsumer, as he undoubtedly does, the effect of composition nd details of manufacture on the thing made, so also does he consumer, if he studies as he should the behaviour of the aterials in service, know better than the producer knows or an know the relation between the composition, the physical roperties or even minute characteristics of the thing made nd its successful use. It is only by the combination of nformation from each of these two sources that perfectly uccessful commercial products can be obtained."

May it not be granted, then, that the true policy to ursue in the fabrication and utilisation of protective coat-ngs for iron and steel is that which has proved successful n other departments of industrial activity—namely, the armonious co-operation in technical matters of the producer nd the consumer? Thus only will the efforts to convert the rude materials of Nature into products useful in the service f man be crowned with success.

ROYAL SANITARY INSTITUTE.

A MEETING of the Institute was held on May 12 in the Parkes Museum, Mr. H. D. Searles-Wood, F.R.I.B.A., residing.

Mr. H. A. Roechling, M.Inst.C.E., F.G.S., read a paper n

The Passage of Excreta through House Drains.

In his introductory remarks the author said he intended o deal with the subject from a practical standpoint, and on he basis of such experiments and observations as he had nade during many years on house drainage systems. It vas his intention also to make use of the experiments under-aken by the Institute in 1893 for the purpose of ascertaining he quantity of water required for an efficient flush of a vater-closet. In the passage of excreta through house lrains, he said it was not so much the actual gradient at vhich the drain was laid in the ground that was of import-nce as the relation between the total height which the water ad to fall in its passage from the flushing apparatus to he street sewer to the total length of the way. The ydraulic discharge gradient, as the author termed it, would vary for every sanitary apparatus fixed in the house, but vas of necessity always steeper than the gradient of the lrain itself. Generally speaking the hydraulic discharge gradients were steeper than 1:10, and from upstairs baths nd water-closets they were as a rule steeper than 1:5. It s of course very essential that the excreta should not lodge n any part of the house drainage system, but should pass as quickly as possible from the water-closet into the street sewer, and the physical problem presented by the transport is a somewhat complex one. A number of conditions, some of which varied continually even in the case of the same closet, had to be considered, such as the actual quantity of flushing water, the quantity and quality of excreta, the atmospheric conditions (cold or warm air in drains), the bends and construction of the drain, the condition of the invert and sides of the drain, &c., &c., but the two conditions which stood out prominently were the limited quantity of the flushing water (two gallons) and the liquid heavily charged with solids. The effect of discharging only a limited quantity of water with each flush was to establish a decreasing head throughout the period. Whilst the discharge from the flushing apparatus lasted the head decreased somewhat slowly, but immediately that was over a rapid decrease set in, which again became slower towards the end of the period. It is owing to the decrease of head that, generally speaking, two flow periods could be distinguished, which were not sharply divided, but merged one into the other. During the first period the flow, as a rule, was fairly regular and uniform, hence the period might be called the "first or regular flow period," but towards the end of the discharge from the flushing apparatus the flow became more irregular, smaller and smaller, until it finally ceased altogether with a mere dribble. To distinguish that period from the first it might be called the "second or irregular flow period." The two periods were the more distinct the quicker the discharge from the flushing apparatus, and the less distinct the slower the discharge. As soon as the flushing cistern was started the water entering the basin carried forward into the soil pipe a portion of the excreta and paper, the rest being removed at later stages of the flush. At the bottom of the soil pipe, especially when that was fairly high, the excreta would be further reduced in size and might be thrown against the sides of the drain, especially where the branch drain entered the main with a sharp bend. They would then be pushed along the bottom of the drain, and so long as the first flow period lasted they would be carried forward through the disconnecting trap into the street sewer. Some of the excreta, however, might have lodged on the invert with paper forming obstructions around them, and if that happened during the latter part of the first or regular flush the force of the water might not be sufficient to remove them. During the second or irregular flush they might be moved a little further down, with the result that at the end they were left behind in the lower part of the drain or in the disconnecting chamber. As the carrying capacity of the water for the same pipe depended very largely on the depth of flow and the velocity, and as these were of necessity best during the first period of flow, it was evident that for the conveyance of the excreta through the drain that that period was of primary importance, whereas the water during the second period ran to all intents and purposes to waste; hence it was very essential that the first period be made as efficient as possible, which could be done by discharging the flushing water all at once, as it were in a rush, thus increasing the depth of flow and velocity.

Referring to the mean velocity of flow in house drains, Mr. Roechling stated that owing to the complexity of the problem involved no formula would give correct results in all cases, and all velocity formulæ must therefore be looked upon as giving only approximate results.

The author then referred to the experiments made by the Sanitary Institute in 1893 with artificial excreta (a mixture of soft soap, cocoa fibre and clay) and pieces of paper. The experiments, he said, showed clearly that for a correct appreciation of the results of a water-closet flush it was necessary to know, in addition to the length and gradient of the drain in the ground, the hydraulic discharge gradient, and that the latter was really the most important factor for the elucidation of the problem. Generally speaking, a short drain (such as a branch drain) had a steep hydraulic gradient, and a long drain (such as the main drain) a flatter hydraulic gradient. Concerning the self-cleansing character of a closet, he held it should not go forth that with a two-gallon flush it must necessarily retain some of the excreta and paper. There were a number of good wash-down closets in the market that would (if properly fixed) give perfectly satisfactory results in that respect. The removal of the excreta out of the closet depended as much on the way in which the water was discharged into the trap as on the quantity of the flush, and when the former was correct no difficulty need be experienced with two gallons. The quantity of the flush and the hydraulic discharge gradient governed the velocity and the depth of flow, and those factors determined practically the transporting power of water flowing in a pipe. It might be that for very steep hydraulic discharge gradients the velocity was of greater moment than the quantity of the flush, but for the range of the experiments, in which the velocity varied from 4 feet to 5 feet per second, it was clear that the quantity was of greater importance than the velocity, and that chiefly owing to the longer duration of the first or regular flow period produced by the greater quantities; the velocity and the depth of flow varying so little, the difference in the results could hardly be due to them. As an instance he gave the case of a 4-inch

Digitized by Google

pipe laid at an hydraulic discharge gradient of 1: 4.41, the velocity and depth of flow being practically the same for a 2, 2½ and 3 gallon flush, so that the better effect of the greater quantity could only be due to the greater length of the duration of the first or regular flow period. The influence of the diameter was, he said, interesting to observe, as only for an hydraulic discharge gradient of 1 in 4.41 (i.e. for short pipes) was the 4-inch pipe slightly better than the 6-inch pipe, but for all other gradients experimented with the 6-inch pipe gave better self-cleansing results than the 4-inch pipe. That result, though against popularly conceived notions which were based on the flow of clean water, admitted of very simple explanation. The depths of flow and the velocities being but slightly different, a 6-inch pipe, presenting a greater width at top water-level, gave the excreta more room to move in and thus afforded less chance for obstructions than the 4-inch pipe. The influence of the length of the drain in the ground could be clearly traced apart from the flatter hydraulic discharge gradient, but assuming that the velocity at the entrance to the drain was the same in a 4-inch or 6-inch pipe laid at the hydraulic discharge gradients of 1: 4.41 and 1: 6.51 (the gradients in the ground being the same, only the length differing), the better self-cleansing effect of the shorter pipe seemed to be due to the increased resistance encountered in the longer pipe.

For practical purposes it might therefore be said that in order to be self-cleansing the velocity in either a 4-inch or 6-inch pipe with a two-gallon flush in five seconds should not be less than 4½ feet per second, and with a three-gallon flush in seven seconds it should not be less than 4 feet per second. The rule, making a fair allowance for the conditions of every-day practice, gave a limiting hydraulic discharge gradient of 1: 4 for a two-gallon flush in five seconds, and for a three-gallon in seven seconds a limiting discharge gradient of 1: 5 either for 4-inch or 6-inch pipes. It should, however, be clearly understood, observed the author, that the rule applied to the drain itself, and not to disconnecting traps.

The total quantity of water used in a house occupied by five persons might be put at 75 gallons in twenty-four hours, out of which 10 gallons would be used for water-closet flushes, 65 gallons remaining for other purposes. It would be clear that the quantity of water used in each house would be more than sufficient to remove, even under the worst condition experimented with, the whole of the matters remaining behind in the house-drainage system after solitary water-closet flushes if the whole of the 65 gallons reached the drain under proper flushing conditions. Unfortunately, however, that was not the case, and on an average not more than 30 gallons reached the drain in proper flushing condition, the remainder, or 35 gallons, being discharged in such quantities and at such rates as to be useless for the purpose. With a 2½ or 3-gallon flush no difficulties need at any time be experienced under ordinary conditions in keeping the house-drainage system perfectly clean and sweet, but the case of a 2-gallon flush required a little further consideration. The worst case here to be inquired into was a house in which there existed only one water-closet on the ground floor without any bath or lavatory, a condition of things frequently met with in cottage property in a provincial or suburban town. Such a case would not lead to any difficulty as regarded the clean state of the drainage system provided the hydraulic discharge gradient of the water-closet was not flatter than 1: 6.5. Where, however, the gradient was flatter than 1: 6.5 it might become necessary to arrange for separate flushing, either with the waste water of the house or the water-supply of the town. At any rate, in such a case in a new house the sanitary authority ought to have power to insist on such arrangements if, after careful consideration of all the facts, they were of opinion that that was necessary. In all other cases no difficulty need be experienced in keeping with a 2-gallon flush the house-drainage system clean and sweet, and where baths and lavatories were in use, especially on upper floors, the system should work perfectly without the least difficulty. It was here assumed that the house-drainage system was used in a reasonable manner, as no provision could be made against wilful abuse or destruction. As, however, even the best apparatus was liable to get out of order in continued use, a periodical inspection of all house-drainage systems was very advisable.

These deductions, made from the experiments of the Royal Sanitary Institute, were amply borne out by every-day experience, which clearly proved that with a well-constructed and well-maintained system neither the drain nor the disconnecting trap did get blocked, and that where that took place a local fault was at work, such as the water-closet apparatus having got out of order or the system being subjected to improper usage.

The author had had under his immediate supervision for a number of years several hundred cottages in a manufacturing suburb of a provincial town, which were inhabited by a continually shifting population, not infrequently of a somewhat doubtful character, and the chief trouble there experienced was the blocking up of the water closets through unsuitable paper, rags and other improper articles. The closets had originally been pan closets, but the urban district council made the owner put up water closets with disconnecting traps in the main drains. In one of the suburbs of London about one-third of the houses were inspected some time ago, with a view to ascertaining the state of the house drainage. Out of 6,745 inspection chambers visited, 6,457 were found to be in proper working order, and in only 288 cases was the disconnecting trap discovered to be blocked up. Expressed in percentages this meant that about 96 per cent. of the traps worked all right, and that only 4 per cent. were out of order. It was added that in 654 additional cases the accident of the blockage of the disconnecting trap was observed to have occurred some time previously. This might have been so or not, but as the blockage was not actually observed during inspection, it was in the nature of hearsay evidence only, and should therefore not be adduced here. Eight months after the first a second inspection was made of the 288 chambers previously found defective, and, in addition, of 216 chambers not previously found out of order. In that case only forty-nine chambers were found faulty, which was a little under 1 per cent. of all the 6,745 chambers previously examined. Taking the results of the second examination first, they clearly showed that it was comparatively a simple matter to remedy the state of things discovered on the first occasion, and that the remedy adopted was so successful that out of 288 cases 239 traps worked quite properly after eight months, and only forty-nine were again found defective. The inference might therefore be made that the faults found on the first occasion were due not so much to principal faults of design as to careless and unjustifiable usage.

Taking the results of the first examination, it did not seem logical to argue that because an apparatus had in 288 cases broken down and had worked perfectly satisfactorily in 6,457 cases, the apparatus itself was bad, and ought therefore to be abolished altogether. If all apparatus that failed in four cases out of every hundred had to be abandoned there would be little apparatus left after a comparatively short time, and the only correct inference from the above figures seemed to be that the apparatus itself was good, and that in the cases of failure the cause was not to be found in the apparatus itself, but in the way it had been used. The results of the first and second inspection therefore confirmed each other and corroborated the experience almost universally gained, that a disconnecting trap fixed and used with care works perfectly satisfactorily, and that where it collapsed that was usually due to a local fault either in the water-closet flushing cistern or in the usage. Indeed, on no other assumption would it be possible to account for the many million traps now in use and for the great numbers that were fixed year after year.

Mr. BALDWIN LATHAM said the paper did not seem to him to be completely satisfactory with regard to the question as to what happened in house drains. Many forms were in use in the country in which there was no flushing through, and yet the drains were clear. The Fowler closets had been quoted, and they were found to act perfectly in manufacturing districts. It appeared to him that most lectures of the kind were prepared with reference to that bugbear of the past, sewer air or sewer gas; but having had a very extensive personal experience in the matter, he believed sewer air was not so deleterious as people imagined it to be, and they knew that it was not the specific cause of typhoid fever. Only recently he had read through an American work on typhoid fever, and there was not one single mention of sewer gas or air as being the origin, but in every case it was attributed to drinking water improperly filtered. The stoppage of intercepting traps, too, was almost unknown, and he believed that given a good trap, with an abrupt fall of water, no fault could be found with them. No mention had been made in the paper of the effect of grease in pipes, and yet it was a most important element in the passage of matter through drains, for an accumulation of grease would gradually stop the channels to the sewers.

Mr. J. PATTEN BARBER said once a dislike had been taken to intercepting traps it was easy to believe all that might be argued against them. He did not think they became so quickly blocked as some people imagined, for he had found

Digitized by Google

that when one discharge of water from a closet did not quite reach the intercepting trap a dam was formed, which, with the second flush, wholly cleared the drain. The first discharge of water might be said to lubricate the drain, and the second, having overcome the inertia of the trap, cleansed it. With regard to the experiments made by the Sanitary Institute, he did not think the right material had been used as artificial solid matter. Cocoa fibre and material of that description was the cause of solid matter adhering to any inequality in the sides of the drain, and sawdust, with clay, was a better substitute. He would have liked to have heard how the velocities of discharges were arrived at.

Mr. C. H. Cooper believed the intercepting trap had been blamed on account of its having been placed in a position never intended for it. He referred to a trap serving the drainage of more than one house. The two-gallon discharge to a water closet would be an efficient flush when the closet was new, but in all cases they had to provide for the far side of the trap, and the closet once having become coated, the force of the discharge was reduced, and in the course of years he believed the two-gallon flush would be found useless.

Mr. H. P. Boulnois said there was no doubt that the paper was clear upon one point—the inefficiency of the two-gallon flush. The speaker had proved by experiments of his own that a larger volume of water was required, and that it should reach the drain in a rush. The question of traps, he said, was exercising the minds of the Local Government Board, and a departmental committee was considering the matter, and speaking personally he would not live in a house the drains of which were without an intercepting trap.

Mr. F. Wood and Mr. W. Kaye Parry also spoke in favour of intercepting traps.

Mr. W. Jennings, alluding to the flushing of drains exercised by bath water, said there was no difficulty in obtaining baths with large outlets, but it was no use having large outlets if the engineer or plumber, for motives of economy, fixed small waste pipes.

Dr. Butler suggested that intercepting traps were not always a success, and there was risk in employing them, since failures were not revealed until the sewage from the drain had percolated through the brickwork.

Mr. H. Freyberg believed that owners of property appreciated disconnecting traps, and he himself thought they should be made compulsory.

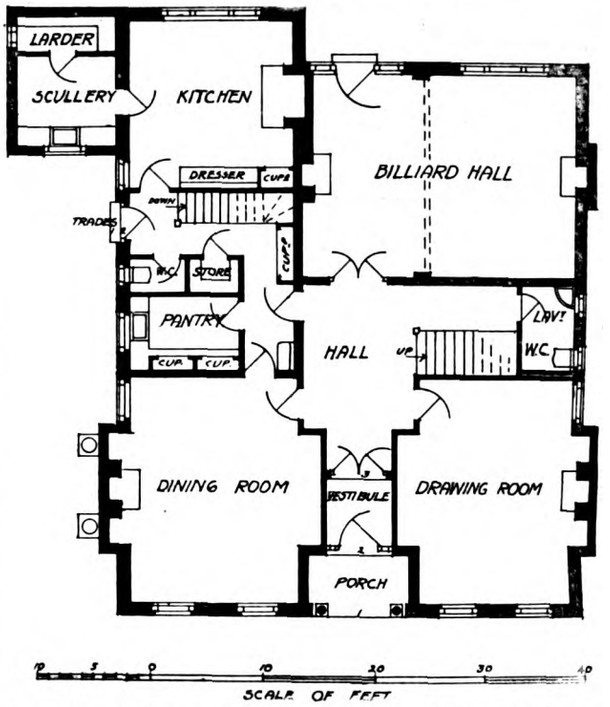
On the motion of the Chairman, a hearty vote of thanks was passed to the author of the paper, by whom it was briefly acknowledged.

ILLUSTRATIONS.

St. Barnabas Church, Mitcham, Surrey.—South-East View.

The church which we illustrate from a water-colour drawing in the Royal Academy will form the second of a group of buildings to be erected to serve the new district of Gorringe Park, Mitcham, Surrey, recently adopted by the City of London School Mission as their special sphere. The church hall, of which a drawing also appears in the Royal Academy, and was illustrated in our issue of July 10 last, was opened by the Bishop of Kingston early this year. The church is cruciform and planned to accommodate 600, with a morning chapel for 50. The materials proposed are dark Crowborough bricks and Ketton stone, with dark red hand-made tiles for the roof. The architect is Mr. Burke Downing, F.R.I.B.A., of 12 Little College Street, Westminster Abbey.

Sedgwick Memorial Museum, Cambridge.—Principal Entrance.

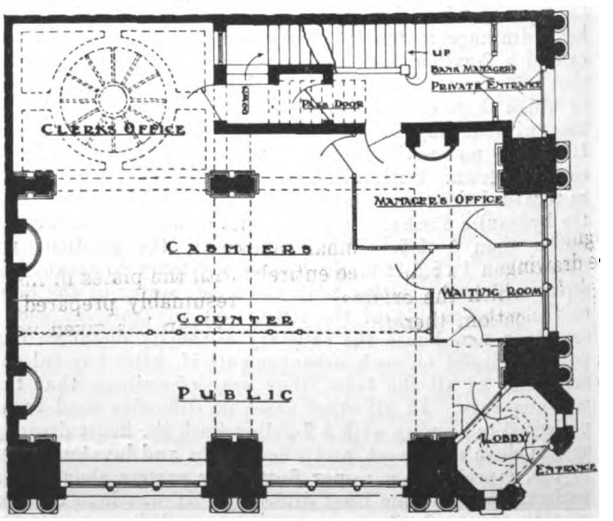


Our illustration this week is in continuation of those in our last issue, and shows in detail the principal entrance to the great museum, with the external staircase adorned with the representations of cave-bears and primitive bisons. We need scarcely repeat that Mr. T. G. Jackson, R.A., was the architect of these buildings.

Details of Kirby Hall, Northants.

Kirby Hall is one of the most interesting examples that we have in England of Early Renaissance architecture, and its details in particular have a peculiar sense of refinement that makes their study valuable. How long it will be before the whole building is lost in decay it is impossible to say, but we fear that the day is not far distant. Our illustration is taken from measured drawings by Mr. W. Eaton, A.R.I.B.A.

House in Heath Drive, Hampstead.



This house has been designed for C. W. Hart, Esq. The plan, while providing the ordinary dining and drawing-rooms, has, instead of the usual small library, a large room opening on to the garden big enough to take a full-sized billiard-table, but so arranged that a library could at any time be formed, and in this case the hall would be extended to the garden. The arrangement of the kitchen and offices is shown on the plan; advantage was taken of

the site being below the level of the road, and cellars and additional larders were placed in a basement. On the first floor are five bedrooms and dressing-rooms, bath, &c. Internally the house is simply finished with detail of Georgian character. Externally the walls are faced with red bricks of pleasantly varied colour, with hand-made tiles to roof. The architect is Mr. C. H. B. Quennell, F.R.I.B.A., of 17 Victoria Street, S.W.

Design for a Bank—Front Elevation.

This building is intended to be executed in Portland stone, with green Westmoreland roofing slates, the

CHIMNEYS AT COMPTON WYNYATES.
From a Sketch by BANISTER FLETCHER.

JACQUES ANDROUET DU CERCEAU.

AMONGST the treasures that we value most in our library is a reprint, published in Paris by A. LEVY in 1872, of DU CERCEAU's "Des plus excellents Bastiments de France," which, in our student days, we managed to pick up cheap at an auction sale when Mr. BATSFORD, *père*, was not present. It is therefore with peculiar interest that we welcome the volume * which Mr. W. H. WARD and Mr. BATSFORD, *fils*, have produced.

JACQUES ANDROUET DU CERCEAU lived in the sixteenth century, being born, as Mr. WARD tells us, probably about 1510, and residing and working in France till 1584, when he vanishes from history. He was, therefore, living at the time when French Renaissance architecture commenced to mature and to shake off the mediæval tradition that so largely influenced the work carried out under FRANCOIS PREMIER. His drawings, therefore, of what as a contemporary he regarded as "Des plus excellents Bastiments" of his time are invaluable, not perhaps so much as records but as intelligent criticism. Our thanks therefore are due to Mr. WARD for bringing before us a selection of the valuable collection of drawings by DU CERCEAU that is preserved, almost forgotten, in the British Museum.

The demerit of these original drawings is that they clearly do not record the buildings as DU CERCEAU saw them, except in a general sense, but as he thought they ought to be if improved in small matters of detail. Nor do the drawings as a rule agree entirely with the plates in his book for which the originals were presumably prepared. The publication, therefore, that Mr. WARD has given us represents DU CERCEAU rather than the châteaux of France in the sixteenth century, in so far as it reproduces the original drawings, but the author has justified the title of his book by collating DU CERCEAU's work with other sources, and so producing a volume which is an admirable epitome of the architecture of the more important châteaux and gardens of France in the sixteenth century. We include advisedly the architecture of the gardens, for to DU CERCEAU and his contemporaries the design of the architectural or formal gardens was as much part of their work as that of the house of which they formed the setting.

Mr. WARD has carefully selected plans and historical data of the buildings illustrated, so that his epitome may be valuable from the student's point of view as well as interesting to the curious.

The qualification of DU CERCEAU to fill the part of an intelligent critic is proved by the fact of his career put before us by Mr. WARD, by the many published evidences of his study of the antiquities of Rome, as well as of the Renaissance architecture of France, and by the records of his designs for the châteaux of Verneuil-sur-Oise, of Charleval and of the Maison Blanche at Gaillon, besides those for ideal châteaux that are given in the present volume.

The drawings in the British Museum collection are excellent specimens of draughtsmanship, and one can only regret that the conditions attaching to the publication of architectural books in this country have necessitated the reduction from the size of the originals that is the only fault we have to find with this very delightful volume.

* *French Châteaux and Gardens in the Sixteenth Century.* A series of reproductions of contemporary drawings hitherto unpublished by Jacques Androuet du Cerceau, selected and described with an account of the artist and his works by W. H. Ward, M.A., A.R.I.B.A. (London: B. T. Batsford, 94 High Holborn, MCMIX. 25*s.* net.)

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

A MEETING of the Institute of Architects was held on Monday evening last at Conduit Street, W., Mr. Ernest George, president, in the chair.

Sir WM. B. RICHMOND, K.C.B., R.A., read the following paper on

Smoke Abatement.

I am gratified that you have asked me to read a paper upon the smoke question, because I feel convinced that a powerful body as ours is can not only do much to convince public opinion upon this important question, but that it could exercise influence upon all governing bodies which require to be pushed to act and to find means to alleviate, if not entirely dismiss, a nuisance, an unenlightened condition of affairs which is detrimental to health as well as to all kinds of property and even also to commerce. It is unnecessary for me to tell you what you all know as well as I do, namely, that smoke and the products, acids, &c., are detrimental to buildings as well as to all hard or delicate surfaces upon which they are deposited.

From the purely æsthetic side of the question there can be no doubt, namely, that a deposit of black upon surfaces which are intended by their designers to appear white contradicts the common sense of all our designs. White shadows and black faces constitute an absurdity even to the tyro, and how much more galling must it be to you when you see your elaborate mouldings and ornaments screaming an ugly lie. It appears to me to be sentimental rubbish which even for one moment defends the colour of that portion of the west front of St. Paul's which has been made the black and unintelligible mass, wholly contradicting Wren's scheme. Gloom is certainly not dignity, nor does dirt and blackness constitute nobility of aspect or add to any historical memories, save those which a firm Legislature ought long ago to have tackled. The black condition of the outside of so many of our public buildings and priceless works of art in architecture is not a thing to be proud of for a moment, but rather to be ashamed of, in that the inertness of public opinion and the insensitive attitude of governing and public bodies which have continued and do continue to delay, not only to legislate firmly, but to see also that their legislation is put in action. Until we have cleaned London from the smoke of factories which do come under the Act it is useless to attempt to tackle the domestic chimneys.

What we have to do is to frame the clause in the Public Health Act in such a way that prosecution is made easy and not difficult, and that could be done by the elimination of the word "black" from the clause, substituting instead "all or any." The London County Council has had this change of wording before it for some little time, accepting a deputation from the Coal Smoke Abatement Society which was listened to with marked attention. I believe that if this Institute would frame, and pass a resolution in accordance with the proposed change in the wording of the clause and send it to the parliamentary committee of the London County Council, the councillors on that committee would be strongly influenced to pass the revision of the word in the clause. Continued expression of public opinion, especially that which is in embodiment hammering at it, is the only way to persuade public bodies to act firmly and promptly. The Local Government Board is steadily remiss in sustaining or supporting the execution of Acts of Parliament in their relations to this Act; the present Minister we hoped to find

Digitized by Google

our friend, but on the contrary all his promises before he got into power are not worth the breath with which they were uttered or the ink with which they were penned. The sustained force of public opinion is the only remedy for Government official apathy and dilatoriness; there is nothing the Government official dislikes more than being prominently shown up in the Press—and it is excellent medicine for him. There is no doubt that public opinion is roused against the monstrosity of London dirt, and, slow as it is, except where pure commercialism is involved, the unthinking public begins to see that smoke meaning waste, and dirt meaning expense, should be, as far as possible, made an unnecessary evil.

One is bound to fear that on a question of æsthetics the abolition of smoke would take a long time to effect, but once prove to the purely commercial mind that his pockets are lighter for it and he will immediately change the tone of his argument. The cost in hard cash to every individual in London arising from dirt caused by smoke and smoke alone is prodigious; the destruction it evokes is terrible. Even what appear to be hermetically sealed cases do not keep it out. Many a time have I glazed, and as I thought finally pasted in the glass in a frame, pasted the backing board and imagined that I had conquered the invasion, when to my disgust, perhaps only a few months after the operation has been completed, I have found the inside of the glass blackened with fine soot powder and the drawing irreparably damaged. To all pictures soot is a deadly enemy even when dry, the deposit left by one black being an essential oil so powerful in its corrosive elements that a solvent which would remove the stain, however slight, would have to be strong enough to destroy varnish and paint. This fact was told to my father by Faraday during the sitting of a Royal Commission when the removal of the pictures in the National Gallery to South Kensington was in contemplation; I think the Commission sat in 1860, since which time we know that South Kensington is now almost as deeply clouded by dirt and smoke as Trafalgar Square, and there, in South Kensington, are treasures for which the Government and individuals have paid hard cash still unprotected by a little manly legislation, a legislation which would not injure but benefit all classes, including the manufacturer-offender, because all smoke is waste fuel.

One of the greatest fallacies is, surely, that stringent laws concerning cleanliness may damage trades. There is only one class which benefits by our smoke, the class of the washerwoman and charwoman; every other trade or occupation is injured, even the very vested interests of the ultra-commercial, because dirt obliges extra labour, and extra labour is expensive. The gas companies might suffer, but what are these among so many? One of the ridiculous travesties of common sense is the fact that the electric light stations in London have been, and some of them are, the chief offenders, creating darkness to produce light! The tram electric stations also are terrible producers of black smoke. From one in my neighbourhood I have seen the smoke travel on the atmosphere for at least a mile; in fact, Bedford Park, a rural district, is severely injured by this plague and selfishness on the part of a company. The Local Government Board declines to take action, though by law it is commanded to do so in default of the district authorities. Why is this? What is at the bottom of it? Votes! perchance; or vested interests; anyway it is disgraceful! The alteration in the wording of the Act would render it easy for magistrates to convict. Under its present reading it is difficult to prove black smoke to exist at all. Whether or no it looks black depends on the tone and colour of the sky, and on its position in relation to the sun at various times of the day. I do not like to venture to state the number of buckets of black water removed from my mosaics and windows in St. Paul's, nor for the quantity of black sediment left at the bottom of the pails after the water had lain still awhile; it was astonishing and aggravating. Now, if this smoke is a nuisance—and as to that there can be no doubt whatever, and that in a large measure it can be removed—it is in the region of a national question, and a far more important one than many Acts of Parliament which only waste the time of the House, and are only such as may possibly, if ever enforced, do some good to certain sections. This is a question which concerns everybody, touches everybody more or less, the poor as well as the rich; for the poor it makes it impossible for their homes to be clean, it makes it impossible for them to grow vegetables in their gardens, it injures their lives, because smoke precludes the admission through it of the most health-giving violet rays; the darkness leads to depression and depression to drink. It is harmful to every building: stone, marble, iron, steel, copper, bronze, even gold is injured by it. Precious fabrics must be kept under glass, and even then they are not immune from damage; it destroys in time the surface of oil pictures; it has injured and still goes on injuring the precious marbles in the British Museum and South Kensington. The sulphuric acid contained in each smut is a poison of great strength; it will rot copper wire in time; cords, string even of strong hemp are eaten into, and many is the picture which has fallen from a wall, the accident being due to nothing but the rotting of copper wires or cords through the action upon them of sulphuric acid. All these things which are just mentioned are known to all of you; it is no news that is told, it is just a reminder, as it were, in a very swift-going period, with many important current enterprises all in the forefront, especially coming to architects, who are the most hampered and shackled section in the whole artistic community by what is called civilisation, which in reality is obstructive to good and noble art, being nothing in reality but commercialism gone mad because agriculture has been wrested from us by machinery. Just a reminder that you, as all of us are prone to do, sometimes may want water and forget the bucket.

You want your buildings to be as you have designed them, and perchance are apt to forget the cause; it takes a good deal of coalition and a still greater persistence of drumming, worrying, to make any Government, and especially the English, attend to needs which do not immediately belong to party politics and seat-saving or seat-getting. If the smoke nuisance were made such a popular cry that it became necessary for any "party" to take it up to get in, we should very soon have the deed done; but when we learn, as we are learning, the hopeless muddles concerning the very existence of England as a country, while amateurs in essential matters rule, how can it be wondered that a great problem such as the smoke nuisance is comes to be regarded as a superficial nonentity?

We are taught by proof that nothing will really move any Government in their snug places in Parliament or officials in their offices but a regular bombardment of public opinion; when that is roused officials become human, and unwillingly are forced to see that the old red tape is rotten, and new must be provided which in its time will become also rotten, then must come again the gyrations of the old wheel of pressure. One thing one always mistrusts—the promises of those who are either in office, or out of office, or going to get office. A Government must be worried while it is in power, and that can only be done by the weight of public opinion.

All and every harm to health, to the joyousness of life, to the preservation of property, public and private; to energies, and to the higher cultivation of the sense of the value of both nature and art, and above all the essential of every stream of light obtainable in this overgrown and artificial city, has been stated over and over again. Statistics upon every branch of the subject are ready to hand, and the most unimaginative Englishman can follow statistics, if nothing else. Therefore what is wanted is the gathering together of statistics which shall show how in various departments of art, industry, health, even morals, this nuisance of smoke is detrimental to the country at large. It will be resisted by monopolists, of course, and by the self-interested classes; it might become a cry of interference with manufacture and labour; but that plea will very easily be broken down. It is an old excuse and one we know of perfectly well, but it is one which, by education of the masses to see for themselves, will very soon find its proper level in the region of untruth.

Before we begin to make an attack on household smoke let us set the law in motion as it now stands, and use all our endeavours, public and private; yet it will be well to bear in mind that there are grates and there is fuel which are practically smokeless. It is too much to suppose, and undesirable also, to look forward to the German stove heating in our houses—that I, for one, hope will never come. The open fire is a grand institution, and there is no goddess of Olympus more snug, more given to good fellowship, than Hestia; still, for general heating of a modern detached house, has the holocaust no recommendations? Gentle diffused warmth reaching, say, from 58° to 60° over the entire house would indeed add to comfort and probably also to health; then the open fire would be just a great luxury, and for it wood might be used in place of coal. I suppose afforestation is a coming thing, anyhow it ought to be; in that case ere long wood should be cheap. And how infinitely more pleasant is the heat it promotes, and absolutely innoxious its

Digitized by Google

gas is as well as its ash, than coal gives off. I wish, and I am by no means alone in wishing, that the poorer classes would combine in tenements, even in streets, and have one cookery place in a given area, and further that all workmen's houses or rows of such were provided with heat as they are now provided with gas or even electric light. All these items in time, if tried now in some district or districts, might become customary. Then we should have begun at the right end for the diminution of smoke from private dwellings. It is no use to legislate till something has been offered equally pleasant as the open fire; but that might come to be regarded as a luxury more than a necessity, if some system of combination or system of general heating were devised and promoted.

To bring my remarks up to a point, leaving out all other points than the law as it stands, I suggest that the Institute should forward a memorandum to the London County Council, and as quickly as possible get it signed by every member, praying that in the clause in the Public Health Act of 1891 relating to smoke the word "black" shall be omitted, or, if not, the "black," "and all other smoke" be inserted. This change of a word or short part of a sentence would enable magistrates to know where they are with the law. Plaintiffs would then only have to prove a nuisance, and not have to prove its colour—an almost impossible thing to do.

Dr. DES VŒUX, in proposing a vote of thanks to Sir Wm. Richmond for his paper, said the greatest obstacle the Smoke Abatement Society had to meet was the indifference of people generally. When he began to fight the cause of the Society he believed every Londoner would be interested in the agitation, but he was mistaken, and the dark days of winter were so soon forgotten that the fight had to be kept up all the year round. A good deal of the fog in London, he said, was attributable to domestic cooking, and it was little use legislating against the nuisance caused by manufacturers if kitchen chimneys were allowed to go on as of old. He could not help believing that if the Institute were to take up even the one side of the question as it related to cooking in private houses an enormous amount of good would result. It was perfectly easy to cook without making smoke, and he believed many people held that certain forms of cooking were preferable when done by gas. If cooking by gas was largely introduced into kitchens he felt perfectly certain gas would be afterwards used for heating the rooms upstairs, and before very long London would be a greatly improved city to live in. The Smoke Abatement Society had gone to the London County Council to have the law changed, and the public control committee had recommended that the word "black" should be removed from the clause of the Public Health Act. A second recommendation of the committee stated that "all chimneys" should include all buildings in which the process of manufacture was carried on, and the chimneys of any building or place carried on under statutory powers. The County Council also sought to include any Government factory or workshop. There were enormous factories at Woolwich or thereabouts, and at certain times of the year the smoke from the chimneys passed over London, doing great harm, and there seemed no reason, therefore, why Government factories should be exempt from law. Recommendations were also being put forward that in certain cases the County Council should be allowed to act either in conjunction with or at the request or in agreement with any of the sanitary authorities. There were certain sanitary authorities which carried out the Public Health Act very well and some did not, and the County Council were desirous of acting with other independent authorities. They also wished to have the power to control the nuisance of smoke from electricity works and refuse-destroyers. The last recommendation was that the County Council should have power to take action outside the district of the London County Council. The proposed alterations in the Act would ultimately have to be considered by the finance committee of the County Council, and the speaker was afraid that that committee would decide the change would be too expensive to carry into operation. If the Institute, however, would bring its influence to bear upon the matter, and show the committee that the County Council was trying to do its duty and that London was behind it, the change in the wording of the clause might become an accomplished fact.

Mr. PAUL WATERHOUSE seconded the motion, and said they wished to thank the lecturer on another issue. Agitations were conducted as a rule not by people who lived in the sublime realm of art, and he felt that they as artists owed a special debt of gratitude to Sir Wm. Richmond for the dirty work and smoky work he had undertaken on their behalf and mankind at large. Something had been said about indifference, and the speaker thought it would be well to analyse it. Among the precepts of their bringing up they were taught that certain things were inevitable and must be endured. The fogs were looked upon as a visitation from heaven; they took them for granted, which perhaps was a mistake. Then perhaps as architects they had another excuse—they were always contending with difficulties. In all their work they found that the whole brunt of it consisted in dealing with troubles, and they rejoiced in them—such things as small sites and light and air cases. One of the London difficulties was smoke. They knew that they had to contend with black upon their buildings, and so a great many architects tried to realise in the first conception of a design how it would look when dirty. They looked upon the difficulty as one to be met and not to be removed.

Sir ASTON WEBB, R.A., agreed that a great deal might be done in the way of gas fires, and he believed that the destruction caused by a smoke-laden atmosphere was a serious hindrance to art, for people would not decorate their buildings with sculpture or paintings when they knew that within a few years the work would be invisible. Marble buildings in London became brown toned, and not only London, but in every big town in England a thick veil gradually spread over the buildings and brought them down to a uniform level. He felt therefore the Institute should be interested in the abatement of the smoke nuisance, and he was sure they would co-operate with the London County Council for a revision of the wording of the Public Health Act. Smoke darkened their windows, degraded their houses and depressed their spirits, and in time would make them commonplace people.

The vote of thanks was passed by acclamation.

Sir WM. RICHMOND, in his reply, remarked that smoke abatement was not only a national question but one which affected the whole world. He had been invited to Paris to help incorporate a society similar to the one in London, and in Rome the authorities had also asked his advice; Venice and Cairo suffered, and he was told that even Japan and India were now affected by smoke. As the leading nation, he held England should set the example in abating the nuisance and so make for the higher civilisation of the world—the promotion of beauty.

THE SOCIETY OF ARCHITECTS.*

(Concluded from last week.)

OCCASIONALLY, sites are purchased on an estate that has been cut up for building purposes, and the plots sold subject to certain restrictions as to frontage line, class of building that may be erected, &c. These questions should be carefully considered, and in making calculations care must be taken to make allowance for the portion of the site in front of the building line, and which cannot be taken into account in calculating available area. Even where there are no restrictions it is well to set the building well back from the road.

Having settled the question of position and assured himself that there is nothing objectionable in the shape of building restrictions, the architect advising a committee should make careful inquiries in regard to what are known as easements; especially should he find out if any of the adjoining owners have acquired a right of light or air over the proposed site that would be interfered with by any buildings it might desire to erect.

Inquiries should also be made of the local surveyor as to drainage, &c., and any special by-laws that might injuriously affect the proposed scheme—*i.e.* some local authorities prohibit buildings being erected of a greater height than the width of the road. This becomes a very important question in the case of a corner site with a narrow side road.

In order to build economically the site should not, if possible, be below the footpath level, the subsoil should be solid "virgin" earth, and any very steep gradients either in the land itself or in the road are objectionable and costly. Made earth is most to be feared on sites ostentatiously advertised as fine deep gravel or sand, since it pays the builder well to excavate and sell these materials and to substitute rubbish which costs him nothing, and for taking which indeed in some cases payment is made to him.

Always avoid a long, narrow site. One approximately a square is more acceptable for a school, for it should be remembered that ample space on all sides of the building

* A paper on Secondary Schools read by Mr. G. T. Forrest on May 13.

Digitized by Google

is necessary. The amount of land necessary for a complete scheme should be carefully considered, especially in growing suburban districts where the price of land very quickly increases in value, and adjoining owners who bought in the early days of the district are apt to ask prohibitive prices. Consider well, therefore, all possible contingencies, and provide enough land for present and future requirements. It need hardly be added that the presence of wires crossing a site forms an encroachment equally with the fixing of a post or standard, and rental for wayleave should be arranged for accordingly.

Type of School Favoured.

Whether a new secondary school shall be a school for boys or girls only, or a mixed or dual school, is a matter for the educationist to decide, and depends in a large extent upon the population of the district and the provision already existing.

The choice between a mixed school and a dual school is a somewhat difficult matter and one which concerns the architect, so that a definition of the two becomes necessary.

A mixed school is one where there is a common staff for both boys and girls and the sexes are mixed in all classes, while a dual school is one where the sexes are not, except in very special circumstances, mixed, but the staffs are interchanged as occasion may require.

Generally speaking, I do not think that many education authorities have favoured the dual arrangement, which, however, has advantages which perhaps it would not be out of place to mention here. In the first place, it is more likely to be acceptable in a district where the co-education of boys and girls above elementary school age is a novelty. Again, it serves to protect to some extent the full development of the boys' section and the girls' section in the school along their own individual lines, rather than making each new feature the result of a compromise between the requirements of the boys and those of the girls. It may also be added that the dual school gives an opportunity to appoint a senior mistress to watch specially over the interests of the girls, an arrangement which has obvious advantages.

Accommodation and General Principles to be Observed in Planning.

Generally speaking, a secondary school can be commenced with a minimum of accommodation—viz. class-rooms, hall, science and preparation rooms; and such things as cookery and manual training-rooms, gymnasium, art-rooms, &c., can be added afterwards.

In small secondary schools it is sometimes arranged that one science-room is made sufficient for the whole of the science teaching in the school, but for a secondary school of any size at least a chemical laboratory, a physical laboratory, lecture-room, preparation-room and dark-room are required.

In some English counties a new system of arrangement has recently been tried with great success. Some directors of education do not agree with the system of taking theoretical work at one time and practical work at another, on the ground that the students get a more thorough grasp of their subject by combining the two parts in one lesson. This system is working well, I understand, and the science teachers after trying it like it. With this view all the science benches are so arranged for the students, and are made so that they serve as tables for taking their notes, the students using stools to sit on during the theoretical portion of the lesson, and during the practical work placing the stools under the benches. Whether sinks and reagents are required to each bench depends upon the extent of the chemistry course, but in ordinary secondary schools it has been found sufficient to have these on the side benches only.

The physical laboratory can be adapted for electrical work if the requirements of the school need it. In boys' schools magnetism, electricity and mechanics are generally taken in this room; and in girls' schools botany, as well as the ordinary physics course. A good balance-room should always be provided and fitted with slate benches set perfectly level for balance work.

A preparation-room is required with easy access to both physical and chemical laboratories. This should be fitted with a good sink, shelves for reagents, and either a separate draught chamber or access to one of the draught chambers in the chemical laboratory.

With regard to the art-room, excellent results in lighting can be obtained by adopting the principle of the ridge and furrow roof where it has not been possible to get a direct north aspect.

As to cookery-rooms, these should be large and airy, preferably at the top of the building. Good scullery accommodation is also required.

The manual-teaching room is better on the ground floor, or isolated, owing to the noise. Practically no fittings are required beyond benches, tool racks and work cupboards.

In girls' schools three changing rooms are required—one for the mistress, one for the girls and one for the other teachers. The girls' room should be planned contiguous to the cloakroom, so that they can change their garments after playing hockey, &c. Arrangements should be made for swimming-baths when money will permit. The head mistress's private room, cloakroom, lavatory and changing room should be *en suite*.

Hot water should always be supplied to lavatories from kitchen fireplace, and a hot cupboard to dry clothes should never be omitted. Lead flats, if possible, should be used for growing plants.

With regard to a room for needlework, if the school curriculum is so arranged that there is always needlework in hand, a special room should be set apart for cutting out and drafting, and fitted with long tables on trestles; but very often this subject is taken in the dining-room, and many lady principals are of opinion that a geography room is more important than a room for needlework, fitted up with places for maps and apparatus. Note that a magic lantern must always form part of the equipment of this room.

In dual schools be sure and keep departments common to both sexes in the centre of the building, thus obviating overlapping.

With reference to the classrooms, the sixth-form room should always adjoin the library, and should have direct access to the room. In some schools the two rooms are divided by a folding partition, thus allowing them to be thrown into one. Where a gymnasium is provided it should have a gallery for scholars, and if the gymnasium is situated outside it is best to make the changing-rooms sufficiently large and easy of access from the playing fields.

Assembly Hall.

It is always desirable to have a principal entrance for the general use of the school entering direct into the assembly hall for public functions, &c. This section is usually set apart for the office, head master's or head mistress's room, committee room, &c. With regard to the assembly hall itself, it is not desirable that it should form a passage way. This point is an important one. The hall should be ample enough to seat the whole of the pupils, with a good margin to allow of sufficient seating accommodation for prize-giving and entertainments, &c. Six square feet per pupil should be taken as a minimum allowance, and any further space will prove of great advantage. If the hall is used as the gymnasium provision should be made for the storage of chairs. Side lighting should be in all cases the rule, as it makes the question of ventilation much easier. One end of the hall should be wainscotted so as to allow of names being painted on, and so prevent those horrible wall boards so often seen and which are so very ugly.

Science Rooms.

No special rule can be laid down for fitting up the science rooms of secondary schools, as the size and character of the school must be very carefully considered in determining the requirements, but as these rooms are so important I propose to consider a few vital questions of laboratory planning and equipment. There are certain general principles to be observed in laboratory planning, and a neglect of these may lead to the production of a laboratory apparently perfect on a cursory examination, yet so defective that to conduct ordinary work therein is a matter of considerable difficulty.

First and foremost, laboratories should be capable of expansion and modification; (2) fittings should be so disposed round the room as to minimise the unavoidable movement of pupils; (3) the arrangement of benches, &c., should insure ease of supervision on the part of the instructor; and (4) the storage accommodation should be ample, and wall space should be left for additional fixtures.

These four considerations should be constantly kept in view, and no fitting should be introduced which to any great extent tends to subvert them. With regard to the general structural nature of the rooms, the laboratories should be lofty, and either top lighted or the side windows so planned that the sill is at least 6 feet from the floor. By this means no wall space is wasted and the light is better diffused. The walls should be wood panelled to a height of 6 feet to enable all apparatus to be easily fixed and easily moved. Glazed tiles or bricks so often employed, though admirable as far as light and ease of cleaning are concerned, are almost fatal

Digitized by Google

when change of fittings are required. It is perhaps superfluous to remark upon the necessity for perfect rigidity in the flooring, the ordinary system of joists and flooring boards being quite inadequate.

Chemical Laboratory.—General Arrangement.

The main desideratum in a chemical laboratory is plenty of room for the students to work. The working benches are either single or double, but single benches have the advantage that all students face the same way and so are under better supervision, but they are very extravagant as regards space. Wall benches are bad and should in all cases be avoided; only when space is extremely limited should they be employed. They obliterate all the wall space and leave no room for cupboards and other fittings. Gangways between benches where students work should not be less than 6 feet; for a single row 4 feet will suffice. Each student will require a minimum bench space of 3 feet 6 inches by 2 feet.

A considerable space should be left clear in front of the demonstrator's table so as to afford room for the students to assemble to receive collectively any remarks from their demonstrator. It is always a decided advantage if perfect symmetry can be secured as an aid in securing the orderly issue and disposal of apparatus and reagents, and reduces the need for movement in the laboratory.

For the same reason reagent shelves other than those on the benches should be placed symmetrically about the room and not all collected into one position, so that no student has to move far to secure any reagent that may be required.

I might mention that before the best method of fitting up the benches can be determined it is necessary to know to what degree the chemical teaching is to be carried. For instance, a very simple form of bench would suffice for a school where few of the pupils would proceed to analysis. At one school I know of they have benches arranged for four students with a plain top, and while a gas jet is supplied to each pupil there is one tap for water and a sink placed at each end which serves for two pupils. There is no partition in the centre (this form being out of date), but a row of white glazed tiles on which to stand bottles. This arrangement is suitable for elementary work, but would hardly be sufficient for a school where there were advanced pupils.

With regard to the detail for bench fittings, each pair of students should have at hand one water nozzle, fixed about 2 feet above the level of the sink, one side nozzle for filter, pumps, &c., one nozzle for condensers, two gas nozzles, terminals for electric current, one balance in a solid and well-made case, one receptacle for rubbish (broken glass, &c.), and space for bottles. If reagent shelves are used on benches, all gas nozzles, electricity terminals, &c., should be recessed under the shelves, raising them on a wood fillet from the bench level. The working space is thus entirely unencumbered, and glass apparatus is not liable to be broken by being pushed against a projecting gas nozzle. In planning the lockers beneath the benches regard should be paid to the maximum number of classes likely to use the laboratory. With regard to the drainage, the V-shaped trough is the most satisfactory. This may be made of 1 or 1½ inch red deal boards joined so as to form a V trough about 6 inches deep, and having protecting fillets to prevent splashing. The trough is thoroughly caulked with a mixture of pitch and tar put on hot. This trough collects the drainage from the sinks and delivers it into a sludge box. The overflow from the sludge box is delivered into a similar trough laid in a chase in the floor, which conveys it to the downspout outside. The gas pipes should be of ample bore and the pressure good, otherwise when many burners are in use at the same time the supply will not be sufficient.

Physical Laboratory.

The main desideratum in the physical laboratory is a table free from vibration and of sufficient width to allow of a student being able to place his apparatus in the proper position. The narrow single bench which many prefer in a chemical laboratory should be avoided. Separate tables suitable for four students should be used, say 8 feet by 4 feet. It is always advisable to leave the bench tops unencumbered. With this object in view, gas taps, &c., should be placed in a row at the ends of the tables, and all tables should be fitted with cupboards underneath. It is not necessary to lay on a water supply to the students' benches; two wall sinks with heaters and drainage boards will as a rule be sufficient. Every physical laboratory should contain a large stock of small drawers, say 12 inches by 3 inches, for the purpose of storing the innumerable small appliances in constant use. Lever handles to the doors of the cupboards should be used, as the ordinary piece of hardware is often difficult to unfasten, and leads to shaking and perhaps injury to sensitive apparatus within the cupboard. All cupboards should have flat tops and glazed doors.

Lecture Room.

The lecture room should be readily accessible from both the chemical and physical laboratories. A space should always be left at the back of the room for a lantern stand, and another on the right of the lecture table for the use of a lantern in optical work. It is a good plan to fit the front of the lecture table with glazed cupboards. If the "Kelvin" sliding blackboard is used, see that the pully wheels are of large diameter; the small ones in common use render the board difficult to move. The electric service employed for adapting the electricity from the supply mains to experimental purposes is all-important, and requires careful consideration from every point of view before the plant is laid down and wiring fixed. It is important that the wires should be accessible and not embedded in the walls. The electric service, however, is of too wide a scope to deal with in this paper.

Desks.

The single desk is the type recommended in the case of secondary schools, and most of the single desks have lockers, though this is not insisted upon. Three different sizes are generally obtained to allow of pupils of different heights and ages. Adjustable desks with complicated mechanism are not as a rule found to work satisfactorily. In one high school for girls which I had occasion to visit some little time ago, the seats or chairs varied in size to suit the desks, and were all separate and not attached to the desks in any way. Some people object to this, but at this particular school the head mistress liked the pupils to be able to move their chairs and sometimes have them close to the desk and sometimes further away from the desk. She also found it a great convenience to be able to take all the chairs from the classrooms to the hall when that room was required for a concert or a large meeting. The gymnastic mistress went round at the beginning of each term to see that each girl had a desk and a chair of the right height. Whatever system is adopted, special care should always be paid to securing desks of practical construction and to their satisfactory placing in the classrooms, inasmuch as the order and discipline in a school are very materially dependent thereon.

Ventilation and Heating.

As the ventilation of a building or school is such a complex question, it is not advisable to discuss the question in a general paper of this description. Whether mechanical or natural ventilation is most suitable is largely a matter of opinion, as there are many strong advocates of both systems. At the present time there seems to be a current of opinion against mechanical ventilation. This, I think, is due to the rather careless methods of many of those who have put in mechanical ventilation without giving it sufficient care, while there are always some people who will come down upon mechanical ventilation as soon as they learn that the building is mechanically ventilated. Perhaps if they had not been so informed no remark would have been made. Of course, there are always schools in which the introduction of mechanical ventilation is quite unnecessary. Except in the heart of large cities, secondary schools for both boys and girls are generally situated in the outskirts, or at all events in the better quarters, where nearly always large open spaces can be easily obtained. In these schools it is not really required. Further, you have in these schools some twenty-five to thirty pupils only in a classroom with a much larger cubic content per child than in the case of an elementary school. All this goes to help the ventilation and renders it less necessary to resort to mechanical means.

The choice of an efficient heating system for a school is always a difficult matter, but experience has taught me that, all things being equal, there is nothing to surpass the ordinary low pressure hot-water system, provided the radiating surface is properly calculated and allowed for. I have never yet seen a properly installed low pressure heating installation fail or give the least trouble. Consequently I have adopted this system almost without exception on account of its economy and efficiency. When we consider the immense advantages of this over all other systems of heating, it is not surprising that lately there should have been such a great development It is necessary, however, to take certain precautions which I shall endeavour to point out.

The following is quoted from a recently published book on school-planning:—"The heating engineer will, of course,

Digitized by Google

determine the amount of piping required to heat the building to the required temperature, making, of course, the necessary allowances for loss of heat through walls, &c." This I believe to be the ordinary procedure adopted, the scheme being left entirely in the hands of the heating engineers.

No doubt this would be all right, provided the lowest tender was not always accepted, but I am afraid that this expression has become a sham, as they nearly always are accepted. On that account, therefore, I have, for a good many years now, discarded the practice of asking heating engineers to submit schemes, for the simple reason that many of them, for the sake of getting the job, cut down out of all reason the radiating surface in their scheme, with the result that I have seen tenders vary from 90*l.* to 180*l.* The lowest tender is accepted, and when the school is opened the heating is a failure. I am therefore of opinion that the architect should invariably get out his own heating scheme, with detailed specification.

To avoid failures, however, the following points should be carefully noted, and I trust I may be pardoned if I deal at some length with this very important branch of school-planning. In manufacturers' lists the boilers are usually rated up to their full power. It is a good practice, after calculating all the pipes and radiators in square feet of radiating surface, to allow a liberal margin of power. One-third margin of boiler power over the actual work will result in a great economy of fuel, and have the further advantage of keeping up the heat for a longer period than six hours without attention.

It is poor economy to put in a boiler that can just do its work. Always select a boiler having a deep fire-pit, as unless the depth of the fire or fuel-holding capacity is in the boiler it is very difficult to get a boiler to burn or keep in twelve hours without attention and keep a reasonable temperature in the apparatus over night. Always see that a safety-valve is fitted on the boiler, and preferably a dead-weight safety-valve—*i.e.* a valve weighted and the weights protected by a cast-iron case. If cast-iron socket and spigot pipes are used, they should invariably be of the medium strength, and it is almost needless to say that in a building of more than two storeys high the heavy should be used.

If wrought-iron pipe is specified, it should be of steam quality and strength and of British manufacture. British practice is to paint the various qualities of wrought-iron pipes as follows:—Steam quality, red; water, blue; gas, black or unpainted.

I believe it has been known for unscrupulous contractors to alter the colour of the various qualities so as to gain the difference in the price, but a good firm would not stoop to a trick of this description.

The reason for specifying British manufactured pipes is that a good many foreign makers supply wrought-iron pipes as steam quality which are lighter than the British makers' gas quality.

Radiators should have perfectly plain, smooth surfaces, as decorated or ornamental radiators only harbour dust.

In selecting radiators it should be remembered that the wider the distance between the sections the better, owing to there being a greater radiating efficiency when the air is allowed free movement across the sections; being wider also admits of easier cleaning. In fixing the radiators to the mains there ought to be a boss cast on the main pipe for both flow and return, drilled and threaded to receive the size of pipe required to supply size of radiator. This makes a permanent and lasting job. A cheaper method is to put on pipe clips or saddles; the disadvantage of this method is that there is simply a hole bored in the pipe and the saddle clamped on with indiarubber joints, such joints not being permanent, as rubber contracts with the heat and the nuts have to be screwed up occasionally, with the result that the rubber flattens out on the pipe surfaces and usually projects over the holes for the radiator supply pipes, very often throttling the supply to the radiators.

With regard to the heating surface in classrooms, &c., having the usual amount of window space required by the Education Department with two outside wall exposures, and to get an inside temperature of sixty degrees with the outside thirty and, say, two air changes per hour, the surface required is fifteen super feet per 1,000 cubic feet, and thirteen for rooms with one exposure, and eleven for halls with no exposures. With three or four air changes increase the heating surface twenty-five per cent.

Usually expansion cisterns are put in far too small; a good practice would call for some reasonable proportion between the size of the apparatus and the size of the expansion tank; up to 1,000 square feet of radiation the tank should not be less than 20 gallons capacity; 1,500, 30 gallons; and 2,000, 40 gallons. Care should be taken that the cistern should have depth, and the ball tap worked in a water line of not more than 4 or 4½ inches.

Circuits should always be valved and the valves placed in the boiler-house and subject to no persons handling other than the caretaker, so that he may know exactly the conditions under which his mains are working.

In arranging main circuits it is advisable not to overload the mains with too much heating surface in radiation. The following I have found by experience gives good results:—Pipe 2-inch bore, 350 square feet; 3-inch bore, 700 square feet; 4-inch bore, 1,100 square feet, on a one-storey building, and so on in proportion.

In considering estimates and schemes (when these are submitted) the architect should carefully examine the plans and select those on the best lines which interfere least with the architectural features of the building.

If these details which I have roughly gone over were adhered to by engineers when tendering, it would be found that the great differences in the amount of estimates would disappear, with the result that better-class work would be obtained. If, however, under these conditions a very cheap estimate was obtained for a scheme, it either means a dead loss to the firm or shoddy and improper work if not carefully supervised.

Artificial Lighting.

In secondary schools situated in large towns liable to fog and where work is carried on in the afternoon or evening the question of artificial lighting becomes one of great importance. Now that the medical inspection of school children has become compulsory, it behoves the school architect to see that the doctor shall have no good reason for tracing cases of visual fatigue to defects in the lighting of the school premises.

Unlike many of our elementary schools, secondary school buildings are usually situated in the suburbs of large towns, or at least in the districts where gas, &c., is obtainable. It would therefore, I think, be out of the question to waste the time of the meeting with any remarks upon oil lamps. Let us rather confine our attention to the discussion of the two best-known modern artificial illuminants, gas and electricity.

First of all let us see the requirements necessary to produce satisfactory results. These are (1) sufficient illuminant; (2) steadiness of the light; (3) colour of the light; (4) light that will give as little vitiation of the air as possible.

Up till quite recently it is surprising how relatively small an amount of consideration has been given to the problem of artificial illumination in schools. During the past *nine* years I have had occasion to visit and report upon a great many schools of different types, and I regret to have to state that the misapplication of artificial light was everywhere apparent, and mark you, misapplication represents actual waste.

Now, however, the competitive development of gas and electricity is steadily educating the architect to a higher standard of artificial illumination. This standard is the outcome of steady development of efficiency in the illuminants themselves as well as in the methods of application. The general question as to whether gas or electricity is the more suitable illuminant for a school is a large one, but after careful study and inquiry I have come to the conclusion that incandescent gas is the better of the two illuminants, and a safer one for the pupils' eyes. I think this will be best explained by defining certain fundamental properties which govern the correct application of artificial illumination.

The even distribution of light is the underlying principle which governs the correct application of artificial illumination. This is essentially so in schemes of interior lighting. To attain this end endeavour should be made to follow as far as possible the distribution and characteristics of daylight illumination—namely, downward and oblique direction, steadiness of the light, and broad diffusion in order to avoid sharp and deep shadows, not, however, seeking to entirely eliminate shadows, as these, by forming contrasts, are helpful and materially assist the eye in its judgment of the form of objects.

In all forms of artificial illumination the intrinsic luminosity or the intensity of the brightness of the luminous surface should be kept as low as possible, or, in other words, the surface from which the light emanates should be as large as possible because (1) the strain on the eye will be as small

Digitized by Google

as possible; (2) the shadows will not be deep, and the difference between light and shade will be reasonable.

Eminent lighting authorities lay down the rule that the maximum allowable luminosity should be below five candles per square inch of illuminating surface. Obviously this means that some method of diffusing the light, either by means of shades or globes, should be adopted wherever the radiant is directly in the field of vision, so that the diffusing surface may be within the limits of a comfortable working intensity. Let us see how gas and electricity compare in this respect.

The strong position of gas as an illuminant is due entirely to the invention of the incandescent mantle, which has so enormously increased the illuminating efficiency. The improvements in lamps and mantles during recent years has been steadily progressive. The colour of the light emitted as in the "Graetzen" lamp is almost white and of considerable penetrating power.

Take electric light. Recently several metallic filament lamps have made their appearance, the most efficient of which appears to be the "Osram." The efficiency of this lamp (32 candle-power) is about 1¼ watts per candle. As the great majority of filament lamps are supplied in clear globes generally insufficiently shaded by reflectors of shallow depth, and are used more often than not within a comparatively short range of the eye, too great regard cannot be given to the serious menace to eyesight which this implies, owing to the image of the glowing filament falling on the less used portion of the retina. The filament lamp is more insidious in this respect because of its low candle-power. The luminosity of an inverted mantle of the "Graetzen" type is probably about 25 candle-power per square inch; therefore, in order to produce the best lighting effect, it is advisable to use suitable glass. This should be of sufficient density to prevent the direct rays striking the eye, obscuring the light, and yet not too dense to obscure too much of the light and so seriously affect the economy. The most suitable globes are those known as opalescent and made of "Jena" or similar glass.

The amount of gas consumed by an inverted burner should be always carefully adjusted so as to get the best results, and if the pressure of gas in the street mains is a varying one, either a volumetric governor of the size necessary to pass the requisite amount of gas should be fitted on each burner, or a pressure governor should be fixed on the meter. In some districts the pressure in the street mains varies as much as 50 per cent., so that without some governing arrangement it is manifestly impossible for the burner to give its best and most economic results.

As an example of the necessity of governing, I have found that with Newcastle gas the best results from a "Graetzen" burner are obtainable when the gas is being consumed at the rate of 3½ cubic feet per hour. This burner, however, unregulated has sometimes been found to consume 8 cubic feet per hour, with the result that the maintenance of glass and mantles has been very excessive; whereas, with ordinary reasonable usage, the number of mantles used for ordinary indoor lighting should not exceed three per annum.

In concluding this paper I may be pardoned if I lay stress on the necessity of designing schools from within rather than from without. To sacrifice the interior so as to get an external effect is insincerity in architecture. It may mean inconvenience to those who use the building, and often results in insanitary conditions prejudicial to body and mind.

Appropriateness in design is the correct aim in art, and this arises where the design is the natural outcome of the purpose for which the building is intended. The present-day public elementary Council school, clean and excellent as it is, if somewhat bare, offers quite sufficient contrast to the homes from which most of the children come, and is therefore well adapted to give them a start on the road to a higher standard of living; but to children, especially girls, accustomed to the refinement of a cultivated home, plain utilitarianism in the erection of a building is likely to present a forlorn and forbidding appearance. Although it may, and indeed does, cost more to make a handsome building, there ought to be set against this the fact that refined and artistic surroundings have a high educational value. Therefore the necessity for a due observance of strict simplicity and practical utility in their erection should not, and must not, prevent the endeavour being made to render the school as a whole, and the several rooms in particular, pleasing to the eye both in form and appearance, whereby there will be called up in the minds of both teachers and scholars agreeable and pleasurable sensations, which may in a measure contribute to exercise a stimulating and exhilarating influence on their faculty of taste and artistic sense.

So much is spent nowadays on teaching art directly that some allowance might be made for influences of this kind, which are none the less strong because imbibed unconsciously.

Mr. P. B. TUBBS proposed a vote of thanks to Mr. Forrest for his paper. He had hoped, he said, to gather a good deal about the planning of secondary schools, but they had learnt more about fittings and the interior arrangement of such buildings. With regard to the question of heating systems, the speaker said he made it a practice in competition estimates for that kind of work to allow a margin of 50 per cent. of the boiler power, and to compare closely the estimates submitted before accepting any tender.

Mr. ELLIS MARSLAND seconded the motion.

Mr. B. R. TUCKER said it was true they had not heard much about the planning of schools, but he thought that perhaps was a detail which could be gained by observation. The information in the paper about ventilation and heating was of immense value, and he agreed with the lecturer that incandescent gas light was superior to electricity in its practical advantages. Birmingham had tried both means of illumination for its art galleries, and had finally adopted the incandescent light. He was opposed to mechanical ventilation, and he would therefore have liked to have heard some remarks upon windows and sashes.

Mr. E. J. NALDRETT said he approached the matter from the point of view of a school committee man, and wished to hear the author's opinion on two points. He had to arrange for the erection of schools to be built at the least possible cost, and he asked, therefore, did the regulations of the Board of Education referred to by the author represent the minimum which must not be fallen short of in all details? The second point was the important question of cost, which had not been dealt with in the paper, and it would be interesting to hear what would be the approximate cost of a school for 150 to 300 scholars.

The PRESIDENT, in summing up the discussion, said they knew that the question of cost depended upon the site on which the building was erected and upon the quality of the school. Secondary schools which might be classed in some instances as technical institutes could not be compared with an ordinary secondary school for girls, so that, taken generally, no definite idea as to cost could be given, but he supposed a school for 150 to 300 scholars would work out at about 35*l.* to 40*l.* per head. With regard to planning, he did not see how Mr. Forrest could have suggested any one plan unless he had brought drawings and pointed out how a school should be arranged. The author had given them the most necessary rules to be observed, but the arrangement of the rooms would be left to the architect.

Mr. FORREST, in his reply, said he did not take a school with an ideal plan and go over it in extenso for the reason that districts and areas varied greatly in their requirements. They found different schemes in different counties, and so an ideal plan which could be followed in every competition was not possible in a paper of that description. With regard to the rules and regulations of the Board of Education, his experience was that they must be strictly adhered to. The cost of schools on the lines he had indicated to accommodate about 200 to 250 children would be about 45*l.* and not exceeding 50*l.* per head. With regard to estimates for work, he said that when a contractor was known to be honest and respectable they had to accept the lowest tender.

NOTABILIA.

THE two opening articles in *Pearson's Magazine* for May are entitled "The First Royal Academy" and "The Charm of the Terrace." The first gives a concise account of the origin of the first Royal Academy exhibition in their Pall Mall premises in 1769. Nine years before, a number of artists who had shown their works in the room of the Society of Arts were so encouraged by the profit of 100*l.*, that as the Society of Artists they continued to organise them for the benefit of the Foundling Hospital. Until 1765 they worked harmoniously. In that year there was a split, and three years later one section reappeared as the Royal Academy. The article is interestingly illustrated. The second article alluded to above is written to show "the importance of an arrangement of terraces in giving an imposing setting to a hill-top house, with some interesting notes on pergolas, without which no garden to-day is considered complete."

THE June number of the *Pall Mall Magazine* is of great interest. It opens with an article by Count Zeppelin, the famous aeronaut, on "The Conquest of the Air." This is

Digitized by Google

followed by "England's Steel Walls," being a non-technical description by Mr. Harold Spender of Middlesbrough—the land of iron and fire, where the material for our Navy comes from. The illustrations for it are not, we are pleased to say, from photographs. The two pictures from the Academy are *Mrs. Astor*, by Sargent, and a study by Sir L. Alma-Tadema. "Algernon Charles Swinburne" is from the pen of the late William Sharp. One of the stories has a couple of full-page illustrations by S. Seymour Lucas.

Acetylene for the current month gives an illustrated account of the installation of an acetylene plant for lighting the village of Down, with 2,000 inhabitants. The present price is 5*s.* per 100 cubic feet, but in spite of this most of the houses and shops of any size are connected with the mains, as well as some of the country houses in the vicinity which formerly maintained private plants. The third of the Cantor lectures delivered by Mr. Leon Gaster on "Modern Methods of Illumination" is given.

"James Cavanah Murphy" is the title of an article by Count Plunkett, director of the National Museum of Science and Art, Dublin, in *The Irish Builder and Engineer*. His chief work was the study of the antiquities of the Peninsula; he spent twelve or fourteen years on the analysis of the Alhambra.

The Invention of the System of Forced Circulation of Hot Water for Heating.

Sir,—In the amusing evidence of Mr. E. T. Hall, F.R.I.B.A., taken by the Departmental Committee of the Local Government Board on Machinery and Engineering Staffs at Poor-Law Institutions, he appears to claim to be the inventor of the system of pumping hot water for warming buildings. The actual words used in his lengthy reply to Question No. 1041, p. 56, are:—

"My practice has been to endeavour to improve the system of heating formerly adopted. . . . I realised this some time ago, and thought that hot water could be pumped from a central station. . . . I first worked this out in conjunction with the contracting engineers without any consulting engineer at St. George's Institution in the Fulham Road in 1900-03. . . . In my judgment it is the best and most economical for heating hospitals, workhouses and asylums."

The last sentence reminds me that when, with an introduction from Mr. J. H. Blakesley, I called on Mr. E. T. Hall at his office, 57 Moorgate Street, on April 17, 1899, *re* the a'Court & Binny heaters and their system of forced circulation for heating by hot water and hot-water supply, Mr. Hall pooh-poohed the principle, and said that his practice was to use a single pipe for both the flow and return, and that he never had any difficulty in obtaining a good circulation; in fact, with the hot-water supply the only complaint (at some institution in Greenwich or Woolwich) was that the water was too hot and scalded the nurses' hands.

I gave Mr. Hall a printed pamphlet (8 pp., 8½ inches by 11 inches), dated 1898, fully describing the system ("invented by Mr. W. M. Binny, and patented by MM. a'Court & Binny," according to the pamphlet), and told him that it was being adopted at the Hospital for Sick Children, Great Ormond Street, by Mr. C. T. Walrond, A.M.I.C.E., the consulting engineer to that institution. This installation was very completely tested by me, and the first part of the report to my clients (Messrs. Burn Bros., who were the sole licensees for the system) is dated August 4, 1899. While one of the tests was being conducted on June 17, 1899, the late Mr. Henry Law, M.I.C.E., and Mr. T. W. Cutler, F.R.I.B.A., representing the Royal Sanitary Institute, visited the hospital, and I explained to them the system and the methods I was adopting for testing it. The system was also installed in the Carlton Hotel in 1899. These dates are all prior to 1900-03, when Mr. Hall says he "first worked this out," and they closely precede that working out, so that probably the information given to Mr. Hall on April 17, 1899, assisted him (possibly sub-consciously) in his labours.

I am not claiming that Mr. W. M. Binny is the inventor; he may or may not be; but what I do wish to make clear is that Mr. E. T. Hall is not the inventor, as Mr. Binny's work certainly was the earlier and was brought to Mr. Hall's notice.

Having referred to the "Minutes of Evidence" in the foregoing connection, it is also interesting to note that Mr. Hall tried hard (answer to Question No. 1038) to impress upon the committee his view that in connection with the construction of hospitals, asylums and workhouses the architect should have control of everything, including all engineering and the direction and supervision of all professional or technical experts.

In spite of his eloquence on this point, which was endorsed by the Council of the Royal Institute British Architects in their letter dated October 19, 1908, to the committee, it is satisfactory to note that the Departmental Committee of the Local Government Board in their report dated January 9, 1909, state (section 51):—"On the whole it seems preferable that, where the engineering work is of an important character, a consulting engineer should be employed directly for the work. He should be engaged jointly with the architect from the inception of the scheme, and should work in conjunction with him."—Yours very truly,

A. S. E. Ackermann, B.Sc. (Engineering), A.M.I.C.E.

GENERAL.

At a Meeting held at Lansdowne House it was resolved to form a committee for the purpose of making suitable recognition of the public services of the late Duke of Devonshire. It has been decided that the memorial shall take the form of a statue of the late duke to be erected at the junction of Horse Guards Avenue and Whitehall, and the site has been given by the Westminster City Council. The execution of the statue has been entrusted to Mr. Herbert Hampton.

Mr. F. Ll. Griffith, Reader in Egyptology, has offered to present Oxford University with 8,000*l.* to establish a fund for the encouragement of Egyptological study in the university, as a memorial to his late wife. The money is to be employed for research, for publication of the results of researches and for travel and exploration, but may not be employed for the stipend of a professor or reader, or for the payment of any lecturer, or for providing lectures on the subject.

Professor Sir Hubert von Herkomer, R.A., will preside at the concluding meeting of the Indian Section of the Royal Society of Arts on Thursday afternoon, the 27th inst., when a paper on the "Function of Schools of Art in India" will be read by the Principal of the Bombay School of Art, Mr. Cecil L. Burns. A collection of drawings by Indian students will be on view.

The Case of Mackison's Trustees *v.* the Town Council of Dundee is again to figure in the Law Courts. In the Outer House of the Court of Session and in the Inner House, on appeal, judgment was given against the pursuing trustees. The pursuers have filed an appeal to the House of Lords, and intimation to that effect has been made to Dundee town clerk. The case will probably be debated before the Lords in October.

The Perth City Council (West Australia) some few months ago invited competitive designs for a new town hall. Designs were received on March 22, and from a cable message received last Monday we learn that the design submitted by Messrs. Grainger, Kennedy & Little has been awarded first prize, the amount of the premium being 400*l.* The cost of the buildings will be about 60,000*l.*, exclusive of land and furnishing. It is expected that an early commencement will be made with the clearing of the site and the erection of the building. Messrs. Grainger, Kennedy & Little are erecting the administrative buildings at the Melbourne town hall, the drawings for which were illustrated in our journal some months ago.

Mr. Lawrence Bright, of Third Avenue, Sherwood Rise, Nottingham, architect and surveyor, who died recently, left 33,914*l.*

The Society of Architects have received twenty-five sets of designs in competition for the travelling studentship, which is of the value of 25*l.* and carries with it the silver medal of the Society. The subject set this year was a secondary school, the details of materials and cost being left to the competitors. The Council have awarded the studentship to Mr. Chas. H. Hudson, of 12 Almeaida Street, Islington, N., an assistant in the office of Mr. A. W. Roques, M.S.A., 10 Basinghall Street, E.C. In view of the high merit of some of the designs and the number of competitors, they have awarded a special prize of the value of 10*l.* to Mr. G. Ll. Evans, 29 Bridge Avenue Mansions, Hammersmith, W., an assistant in the office of Mr. Arthur W. Sheppard, A.R.I.B.A., 43 Chancery Lane, W.C. The drawings will be on view at the Society's premises, Staple Inn Building, Holborn, W.C., for one week commencing June 7, when admission will be free. Afterwards they will be exhibited in various provincial centres.

The Architect.

THE WEEK.

THE special general meeting of the Royal Institute of British Architects held on Monday last for consideration of the Council's proposals for the revision of the by-laws under the new Charter made good progress, thanks to the able chairmanship of Mr. EDWIN T. HALL, and passed twenty-seven by-laws in an hour and three quarters, an average of just under four minutes per by-law. This very satisfactory progress was largely due to the handling of the meeting by its chairman, but principally to the generally non-contentious matter of the by-laws considered and to the maintenance of the spirit of give-and-take that has been characteristic of all meetings of the Institute since the scheme for the latest new Charter was brought forward.

THE meeting was, too, a justification of the principle that only Fellows should be allowed to vote on the making of by-laws. Most of the talking was done by Associates, and when any Associate had a reasonable amendment to suggest he always found two Fellows to propose and second it, so that, even though voteless, the Associates as well as Fellows have their views represented in the by-laws as adopted.

THE first debate occurred on the question of nomination for membership of non-Metropolitan architects and members of the Architectural Association, which, as the existing by-laws stand, might be made by non-members of the Institute, or even by paid officials. Although some objections were urged the principle was adopted of giving the power of nomination to non-members but denying it to the paid officials.

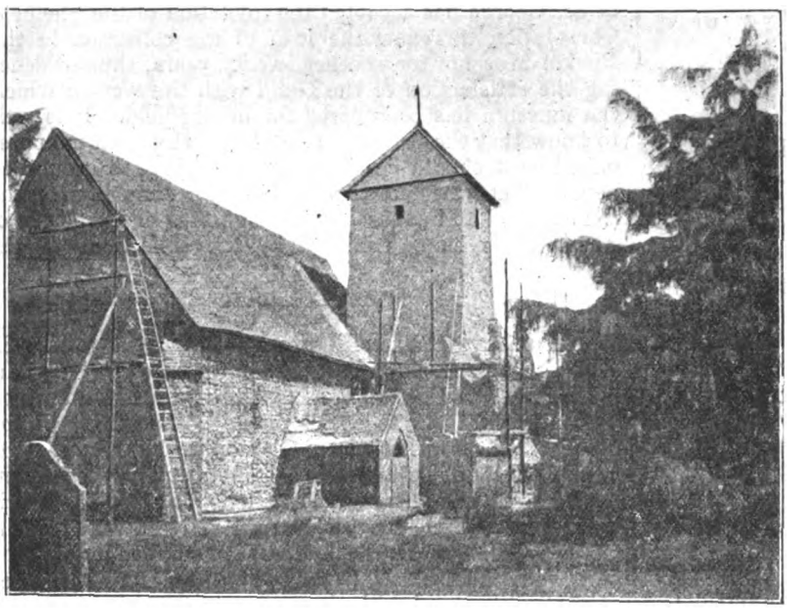
A GOOD deal of time—more than was really necessary—was spent over the exact wording of the by-law regulating the election of Fellows by the Council, but at length it was decided that at least twelve members of the Council must vote in favour of a candidate. As it is professedly admitted on all hands that the election of a Fellow by the Council is to be a very rare and exceptional honour, there would, we think, have been no valid objection to requiring the unanimous vote in favour by all the members of the Council present, even if the whole forty happened to turn up. The chairman made a slip by suggesting that there might be a member of the Council present who would not vote either for or against a candidate. Any architect who cannot obtain the approval of every member of the Council for his election is unworthy of the high honour of being elected by the Council alone.

THE by-laws regulating the election and privileges of Licentiates were passed in double-quick time. There are no Licentiates at present. An attempt was made to impose an entrance fee, and a general impression seemed to prevail, in spite of the chairman, that the Licentiates are being admitted at too cheap a rate; but nobody cared to press the point, and the Council's suggestions were adopted.

THE last by-law considered was the first of a really debatable character, being that regulating the constitution of the Council. The proposal by the Council that two past-presidents shall be included, thus raising the membership from thirty-eight to forty, was adopted after the defeat of an amendment limiting the proposal to the two immediate past-presidents. Then came the glorious victory of the Associates—voteless but not voiceless; they raised the number of Associate members of the Council from four to six. Loud cheers and a prompt decision that enough had been done for one evening. So the meeting was adjourned.

ALTHOUGH there was never much doubt about the matter, it is a cause for congratulation that the Guild of St. George has accepted the invitation of the Sheffield Corporation to renew the loan of the collection in the Ruskin Museum for another twenty years, thus evidencing the satisfaction of the Guild with the way in which the museum has been cared for in Sheffield. It is well to know that the privilege accorded to the town is appreciated as it should be, and thus that there is ground to believe that what RUSKIN wished—an ennobling of the thought and an increase of the happiness of the people of Sheffield—is being achieved by the collections of the Master.

THE Surveyors' Institution at their visit to Cardiff discussed a paper on "State *v.* Estate Forestry," by Mr. S. H. COWPER-COLES, Lord GLANUSK's agent, in which the author seemed to speak rather despondingly of the prospect of afforestation in Glamorganshire, where the waste land is subject to manorial rights and privileges connected with hill farms and small holdings, while in his experience planting above a level of 1,200 feet was not satisfactory. He thought the land was not suitable for growing hard wood and that they would be limited to coniferous trees of exotic type, and with these they had had little experience. Although they could grow magnificent larch they could not sell it in the Welsh coalfield; it went mostly to Lancashire. One good point that Mr. COWPER-COLES made was the value to water catchment areas of afforestation, as attracting a larger rainfall and ensuring a steady and constant supply of water.



ANOTHER subject considered by the Surveyors was the amendment of rating law and procedure, particularly as regarded valuation for assessment by unpaid parish officials, subject to local influences, rather than by professional surveyors. It was urged as desirable that all property should be valued once in five years, but not that there should be a quinquennial valuation for the whole valuation area at a fixed date.

AT the annual meeting of the Liverpool Committee for Excavation and Research in Wales and the Marches, Professor JOHN L. MYRES, the hon. organising secretary, presented the first annual report on the preliminary surveys that had been made in Chester and at Caerleon-on-Usk, and foreshadowing the coming work of excavation at Caerleon and at Caersws in Montgomeryshire, two of the most important Roman stations in Wales, from the exploration of which great things are hopefully anticipated.

THE Scottish Presbyterians in London have had the laugh of the County Council. A notice board outside a Presbyterian church bore a representation of the burning bush with the inscription *Nec tamen consumebatur*, and the minister was one fine day requested by the County Council to take out a licence for using armorial bearings. In acknowledging the receipt and protesting his ignorance that for this notice board a licence was necessary, he suggested that an official should be sent to determine whether another ornamentation within the church should also be described as an armorial bearing. This consisted of two Scotch thistles, with the motto, *Nemo me impune lacessit*. The cream of the joke is that no official was sent, but the minister received a letter, we understand, saying that his "explanation" was satisfactory.

MR. JUSTICE JOYCE has granted an injunction restraining the trustees of the Wesleyan Twentieth Century Fund from building the new Wesleyan Memorial Hall, now in course of erection from Messrs. LANCHESTER & RICKARDS's design, to such a height as to interfere with the access of light and air to the Westminster Hospital. The learned judge appears to have based his decision on a report by Mr. JOHN SLATER respecting the effect of the new Wesleyan building as intended on the lighting and sanitation of the Hospital.

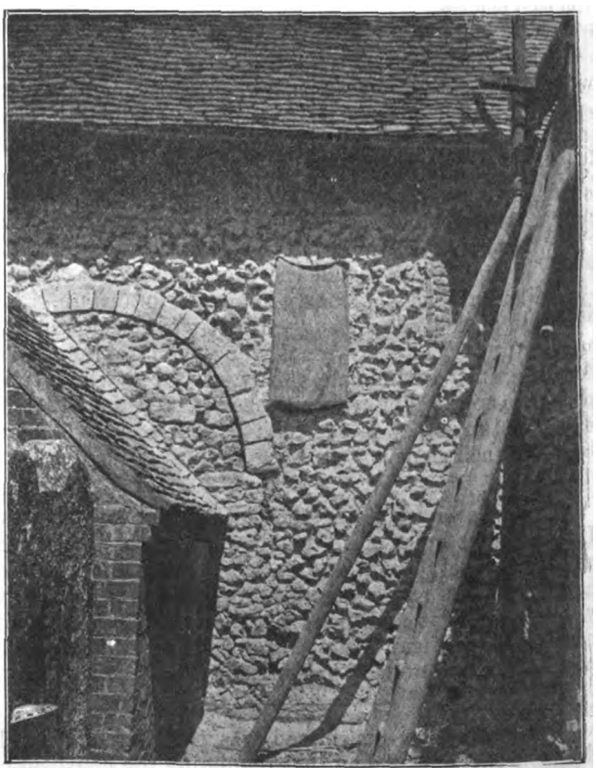
KINGSDOWN CHURCH, KENT.



DISCOVERY OF AN ELEVENTH-CENTURY FRESCO.

UNTIL quite recently the little Kentish church of St. Edmund, King and Martyr, at Kingsdown, was an ugly-looking building covered with the brown Roman cement compo, beloved of churchwardens in the early years of the nineteenth century. This plastering having fallen into a sad state of disrepair, the present rector, the Rev. F. W. Warland, determined to have it stripped off, with the intention of pointing up the underlying masonry if in sufficiently good condition. Before the work was commenced the church appeared to be merely a badly treated fourteenth-century building, and, as described in Murray, "very plain, and without distinctive character." A small nave, with smaller chancel, a few fourteenth-century windows, two of them in the north wall with fragments of contemporary glass; a hideous gap at the west end, with wooden frames that had evidently taken the place of the original tracery; a fifteenth-century Perpendicular traceried window in the south wall of the chancel, an inserted red-brick window, with random fragments of heraldic glass, traditionally brought from a neighbouring manor-house and clearly originally bearing the arms of the De Lucys; and a small square tower, of indeterminate date, on the south side of the nave, formed all the architectural features.

The stripping of the old compo has revealed much of the lost history of the church, as well as some interesting features. The west window was a three-light one, part of its mullions and sill having been brought to light, and from the character of its scoinçon arch, without doubt contemporary with the two-light windows in the north wall of the nave, and, like them, filled with reticulated tracery, and therefore of about the date A.D. 1325.

It is, however, in connection with the present south wall and the tower that the most interesting and important discoveries have been made. In stripping the south wall, the workmen discovered in the wall four semicircular cut stone arches with squared edges, two in the nave, one between the nave and tower, and one in the south wall of chancel. These arches are clearly insertions in an earlier work, and for safety have a considerable space of the older wall left between as piers. In the east wall of the tower is a lofty semicircular headed archway with plastered jambs and soffite lined out in red line, with quâ stone-jointing decoration. This arch has later been filled in, and a smaller doorway formed in the filling. There seems to be some evidence of an archway on the west side of the tower, but the indications are not indisputably clear. On the south wall has been discovered a small semicircular headed window, of which more anon.

The most thrilling discovery of all is that of a small window in the south wall of the present nave, with a semicircular concentric splayed arch. The external opening is six inches wide and thirty inches high, the internal three feet two inches wide and five feet five inches high. On the internal splay is the fresco decoration which we show in our illustration. This is executed in yellow, red, and brown ochres on a white ground, and is in a wonderfully-good state of preservation. The *intonaco* is very thin, and the artist has evidently worked at full speed to complete his painting in time, for in colouring the soffite he has splashed the jambs and left the splashes. The subject of the picture is clear. On the right jamb (west) Abraham is about to slay his son, and the uplifted weapon is apparently the jaw-bone of an ox. One of the parishioners, we hear, suggested that it might be "Samson killing the giant with the jaw-bone of an ass," but the left-hand picture clearly corrects this somewhat involved explanation. Abraham is carrying the wood and Isaac the lamb for the burnt sacrifice about to be offered on the altar shown between them. The first indication of the presence of this painting was obtained from the stripping of the old plaster outside the church. The external arch was exposed, and the filling being somewhat loose was pulled out for resetting, when part of the painting appeared. Interested and excited by the discovery, the builder obtained the rector's permission to cut away the internal plastering, and was thus able, with care, to remove the filling and reveal the painting.

KINGSDOWN CHURCH, KENT.—Part of South Wall.

Now we come to the data that enable us to form our diagnosis. The damage to the picture on the right jamb was done in the insertion of one of the four semicircular arches to which we have above referred, and the filling in of the window was probably contemporaneous with the formation of these arches, the haunch of one of them just penetrating the right jamb. We must here explain that the whole church is built of undressed flints, with the

Digitized by Google

exception of dressed stonework to architectural features. The flint-work above the inserted arches and the small window in the south wall shows distinct lines of coursing and a herring-bone bonding of the rough flints in adjacent courses. The tower has flint quoins of carefully selected stones, admirably square though undressed. The small window in the south wall of the tower, of which we have already spoken, and which is slightly wider but otherwise of about the same size as that with the fresco painting, has its arch built of carefully chosen natural flints of flat but wedge-like form, forming natural voussoirs. Although freestone is used on the outer edge of both these windows, there does not appear to be any indication of their having been glazed at any time. The four inserted stone arches are of chisel-worked freestone, square-edged. The flint-work masonry of the north, west, and east walls is pure random rubble, without any trace of coursing or herring-bone bonding.

On these data we base the following diagnosis. The present south wall from end to end is part of a church built during the first half of the eleventh century, probably between A.D. 1025 and A.D. 1050. The window with the fresco was an original one of this church and the painting was executed within the dates we have assigned. Although we found this opinion chiefly on the architectural evidence, it is we think supported, as may be seen in our illustration, by the character of the figure drawing and costume. Later in the eleventh century, possibly about A.D. 1080, the original church was enlarged by a southern addition, and the four semicircular arches made the arcade between the new and the old. The fresco painted window was filled in at this time, partly, as we have already pointed out, for safety, and partly because it was no longer in an external wall. There are straight joints between the east and west walls of the tower, and the original south wall and the tower therefore was probably part of the later eleventh-century work. In the fourteenth century, probably about A.D. 1325, the older eleventh-century building was pulled down, with the exception of its south wall, and the west, north and east walls of the nave and chancel were erected. At this time, if not before, the extension made in the latter part of the eleventh century was also pulled down, for there is a fourteenth-century doorway inserted in the south wall. In the early part of the fifteenth century the traceried window on the south side of the chancel was inserted, and later in the same century the small red-brick windows in the nave, with the fragments of the DE LUCY glass.

Thus the removal of the old compo has opened up a very interesting piece of architectural history, as well as brought to light a remarkable example of early fresco painting, which owes its preservation to the fact that in the eleventh century there was no Society for the Protection of Ancient Buildings, but a disregard of the work of their predecessors by men who felt that provision for the requirements of their own day was the foremost consideration. The principle then adopted seems to have actuated all subsequent custodians of this little church down to the nineteenth century, for it would be difficult to find in a building of its size more complete indifference to the art of the past than is here exhibited. And yet it is due to those whom some would call the "vandals" of the latter part of the eleventh century that we, to-day, are able to see in its pristine freshness the production of an artist who lived and worked before WILLIAM OF NORMANDY invaded this country. We trust that proper steps will be taken to preserve this remarkable example of early English art.

The Plans prepared by Mr. R. S. Lorimer, A.R.S.A., F.R.I.B.A., for a chapel for the Order of the Thistle, to be constructed at the south-east corner of St. Giles's Cathedral, Edinburgh, alongside the Royal entrance, were approved by the trustees. On the 22nd inst. Mr. Lorimer and the trustees were received by the King at Buckingham Palace. Mr. Lorimer explained the proposed plans to the King, who looked into every detail, and entirely approved of what was proposed as far as regards the structure.

COMPETITION FOR MIDDLESBROUGH PUBLIC LIBRARY.

TWO hundred and three sets of designs for a Library to cost 12,000*l.*! It must be very encouraging to a committee to have such a response to their invitation, or, on the other hand, it may point to a lamentable want of work amongst the architects of Great Britain and Ireland, for there are plans from England, Scotland, and Ireland—but none from the Colonies. So it must be presumed that as the successful man has to pay his own travelling expenses, these fortunate islands are at present free from that form of competition. Most of the designs comprise four imperial sheets of paper, and many six or seven, so that there are more than a thousand sheets of drawings for a conscientious assessor to examine.

Having said this as to the amount of work done, it is a natural sequence to the quality, and here there is little cause of congratulation, for at least 60 per cent. of the designs are utterly unsuitable for the purpose, whether judged by fitness of plan or architectural quality in the elevations and sections; whilst as to the draughtsmanship, those of our readers who have seen the quality of the work shown in the drawings of a Continental competition will be inclined to despair. It would be a kindness to many of the competitors to tell them frankly they have mistaken their vocation. Many are the eccentricities displayed to attract attention. One set has the walls a lovely rose-pink (think of rose-pink walls in Middlesbrough!), the stone dressings a delicate green, and the roofs a vivid Prussian blue, whilst many others seem to have considered their plans an opportunity for a chromatic display, colouring the different rooms in striking blues, greens, reds, and yellows, with the result that it is really difficult to disentangle the plan at all. Another curious feature that has degenerated almost to a fantastic trick is to use so thick a line both for prominent and subordinate features that the drawing becomes confused and it is necessary to rule in lines of centres, either columns, arches, or pediments, well into the sky-line and deep into the foundations to help the ordinary mortal to see what is meant; and others go one better by outlining the mass of thick lines with a stout river of black, measuring quite one-sixteenth of an inch—or to eighth scale, six inches. Surely these are signs of degeneracy.

A further division from the before-mentioned good and bad might be made of those who ignore the instructions issued by the Library Committee, and it is a moral question whether an assessor should not at once rule out all those who fail to comply with expressed particulars. It is certainly hard on those who flog their brains to meet the requirements and honestly abide by the conditions. Some of these need to be borne in mind in forming an opinion of the merits of the work displayed; and one in particular seems to have given great trouble—viz. the requirement that the boys' and girls, rooms should be served at a common counter—the two rooms divided by a glazed partition—but each part to have a separate entrance. Again, one room is asked for 23 feet by 10 feet for receiving, repairing, and cataloguing, and to be on ground floor. Both these items are very differently provided for by the competitors. The first seems to have caused many to put extra entrances to solve the difficulty, and the second has been met in several cases by putting separate rooms and on different floors.

The design placed first is No. 171, by Messrs. RUSSELL & COOPER, of London. The news-room is placed at the spot specified in the conditions, and is divided from the main block by a strip containing the janitor's and receiving-room—the janitor facing Grange Road and the receiving-room the back passage. Nearly opposite the centre of the news-room and at right angles is the main entrance, showing a well-designed entrance-hall having doors leading to borrowers' space and ladies' room on either hand, whilst the stairs face anyone entering. Between the stairs is a double door leading to the news-room—no doubt very happily placed, but not strictly in accordance with the conditions, which stipulate for *no* public connection between news-room and other parts.

Digitized by Google

The lending library is well arranged, and the children's library beyond has the book store in the centre (and so in touch with the general book store and attendants) and boys' and girls' rooms on either side, with a corridor and separtte entrance for this department. This is not strictly in agreement with the conditions, which stipulate for boys' and girls' rooms divided by a glazed partition—not by a book store.

On the first floor the librarian is placed over one of the juvenile rooms, and there is a small staircase at the end of children's corridor by which he may go down, but the position of this room is not good. To reach the main lending library he must either go through the juvenile book store or traverse the whole of the reference library and go down main stairs to reach the news or ladies' room. Over the other juvenile room is a cataloguing room, stipulated to be on the ground floor, but placed on the first.

The reference library has deep galleries on either side, projecting 12 feet into the room, and as there are no windows under these the book recesses will be very dark, but at a distance of 18 feet from the floor is a range of long shallow windows—the only light to this large room—and the before mentioned deep galleries cut even that off from the greater part of the floor. The conditions stipulate for top light only to this room, and no windows in wall. Windows are shown and no skylight, which is what most people understand by "lighted from the roof direct." The elevations are simply treated in brick with white stone dressings, and are not particularly pleasing. One long roof and ridge runs from end to end. There is the usual break in the elevation of two very broad stone pilasters carried up to cornice and joined above it by a familiar rusticated semi-arch, and the windows of the ground floor lending library float in the mass of brick work between these breaks. This design could be carried out for the money provided.

No. 13 is placed second, and is by Messrs. Wenyon & Potter, of Dudley. It has some points in common with the one placed first, viz., the juvenile rooms are at the same end, but each room has a separate entrance from the street, and the book store is behind the two, thus forming a room divided by a glazed partition as asked for. The main entrance centres with news-room, and has stairs on either side, and the not-asked-for door into news-room between. The law library on first floor is over the juvenile rooms, and has a curious feature, a large oval cut through the floor of store above, thus allowing the light to reach it from a skylight many feet above. The elevations are honestly treated, but look somewhat meagre and insignificant. Whether there is a roof light to reference library is not clear from the plans. This design could be done for the money.

No. 83 is placed third, and is by Messrs. Cooper & Slater, of Blackburn. The juvenile room difficulty is solved by putting it at the Grange Road end, with separate external entrances, but there is no light to the book store. The gallery in reference library has windows in the wall, and without a roof light this room would be dark. The elevation is much more imposing than either the first or second designs, and has a tower, but could never be done for the money.

No. 49, by Mr. W. Haywood, of Birmingham, is a very striking design, but it could not be carried out for the sum provided.

No. 153, by Messrs. Clark & Moscrop, of Middlesbrough, has a very dignified elevation, but the plan is not so good—four public entrances are too many for such a building.

No. 40, by Messrs. Wills & Anderson, of London, is a courageously simple treatment, very refreshing to look at after many of the grandiose attempts, but is perhaps a trifle too rustic for a public building in a large town.

No. 3, by Messrs. Clapham & Tanner, of London, has many good points in plan, but the main entry is poor and narrow; the girls' room is too deep from window to be well lit, and the janitor would depend entirely upon artificial light. The elevations are treated with long bands of alternate stone and brick, and would not be satisfactory.

No. 58, by Messrs. Wallis-Bowden & Grant, of Westminster, has a very simple yet dignified elevation; the ladies' room would be dark, however—it is too deep from the window wall.

No. 91, by Mr. C. E. L. Parkinson, of London, must be meant for a Gothic joke; surely the author never meant it as a serious contribution.

No. 73, by Messrs. Leeming & Leeming, has a very nice elevation, but the main entrance is so restrained that it would have to be looked for. There is a tortuous passage, not asked for in conditions, between side and main entrance, and a very deep gallery in reference library that would make much of the floor dark.

No. 47, by Messrs. Withers & Meredith, has a pleasing elevation, but rather spoilt by putting the bases of the large columns almost on the ground; a plinth would much have improved it. The arrangement for juvenile department is not good; a lobby separates them from the counter and therefore from efficient supervision.

No. 141, by Messrs. Mould & James, of Newcastle, has a good elevation, but the public would not easily find the entrance to the main thing—the lending library.

No. 184, by Mr. E. F. Smith, of Walton-on-Thames, has made a queer slope to the back wall of the lending library, and as his plan is the only one showing this it is to be presumed that some measurements on the plan of site have been misread.

No. 202, by Mr. G. Drysdale, of London, is another merry trifle; why make the elevations difficult to understand by putting the Dunning Street and Grange Road elevations in line and joining them up by a cleverly drawn imagination of blast-furnaces and chimneys?

No. 96, by Mr. H. Lord, of Manchester, has a good plan, but the elevation is treated strangely, for blank walls are shown where windows ought to be, and rooms lit from the roof for the sake of balancing the elevation. It is true the reference library is required to be entirely lit from the roof, but that scarcely seems reason enough to do the same thing to others. Mr. Lord is not the only competitor who does this for symmetry; indeed, very many do it.

No. 70, by Messrs. Arnott & Morrison, of Edinburgh; but five entrances are too many for a building of this character. The elevation honestly grasps the difficulty of the blank wall of reference library, and treats that block as a separate feature.

No. 154, by Messrs. Vaux & Mark, of Sunderland, is so wonderfully coloured on plan that the ordinary eye cannot readily grasp its good points, and as the sections are treated in the same way—that is, separate rooms are coloured in different and very vivid colours—they are even more distressing. The elevation is very pleasing.

No. 39, by Messrs. Child & Watts, of Nottingham, is a thoughtful and pleasing design, but the plan is spoilt by a poor entry, and the double attic story above main cornice is unrestful and fidgety.

No. 123, by Mr. T. G. Davidson, of London, is a picturesque treatment of the subject, but the windows are too small for library purposes.

No. 72, by Mr. A. McKewan, of Birmingham, is a nice design, but strangely got-up with red-brown lines and a greenish yellow wash; what the materials are to be is left to the imagination; the conditions say the elevations may be coloured to indicate materials, but this seems too liberal a translation.

No. 8, by Messrs. Hicks & Charlewood, of Newcastle, has a striking elevation, and here again the difficulty of the reference library has been honestly treated, but several points of the plan are open to criticism, such as a poor entry for a public building, and rooms too deep from the window wall.

No. 177, by Messrs. H. Jones & Cummings, of Westminster, is very original and picturesque in treatment, but the broad frieze, so effective in the drawing with its lozenges of brick, would not be very satisfactory in execution.

No. 78, by Messrs. Cox & Williams, of London, is a merry design; it can hardly be taken seriously. It is beautifully got-up, has many good points in planning, but windows really are a necessity—even for a library.

Digitized by Google

No. 90, by Messrs. WARWICK & HALL, of London, is perhaps the most architectural design in the competition. It is scholarly and refined, and would undoubtedly be one of those buildings that would not tire with constant acquaintance. The truncated gable strikes a wrong note, and there are some faults in the plan, notably a rather poor and narrow entrance hall, and the juvenile problem has not been satisfactorily dealt with.

No. 43, by Mr. J. H. MARKHAM, of London, is a very pleasing design, well got-up, and is particularly noticeable for the fact that there are no string-courses or cornices. It is doubtful, however, whether in a town such a treatment would not be somewhat bald and flat.

No. 98, by Mr. J. B. FULTON, of London, is very pleasing. The elevation is very good indeed; the centre feature is a trifle squeezed up, and windows are omitted for the sake of balance.

Altogether the Middlesbrough Corporation have good value for the premiums. Deducting the first premium as it is merged in the commission, there is 50*l.* spent for about 1,000 sheets of drawings, or, say, one shilling per sheet. As Whatman paper costs 4*d.* per sheet, and most drawings are on strainers, it is evident the architectural profession is the most generous one in the world.

GRIMSBY TOWN HALL COMPETITION.

THE Competitions Committee of the Royal Institute of British Architects have received satisfactory explanations in respect of those conditions of this competition which appeared to be objectionable.

BERKSHIRE COUNTY COUNCIL OFFICES COMPETITION.

WITH regard to the conditions of the above competition, the Council of the Royal Institute have received a satisfactory reply to their suggestions for the amendment of paragraph 1 of the printed conditions.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

THE annual dinner of the Royal Institute of British Architects was held on Wednesday evening last in the Whitehall Rooms, Hôtel Métropole, Mr. Ernest George, President, in the chair.

Among the guests were the Ven. Archdeacon Sinclair, Sir Lawrence Alma-Tadema, Sir Ernest Waterlow, Sir Henry Howorth, Sir Melvill Beachcroft, Sir Aston Webb, Sir James Linton, Sir William Emerson, Sir Charles McLaren, M.P., Sir John Taylor, K.C.B., Sir Henry Tanner, Mr. Frank Dicksee, R.A., Mr. J. S. Sargent, R.A., Mr. Thomas Brock, R.A., Mr. Henry Morris, Mr. Philip Norman, Mr. Philip Morrell, M.P., Mr. P. A. Molteno, M.P., Messrs. Maurice B. Adams, J. Macvicar Anderson, F.R.S.E. (Past President), John A. F. Aspinall, R. Frank Atkinson, Maxwell Ayrton, Herbert Batsford, W. C. Beetles, B. E. Bell, H. F. Bidder, Professor Reginald Blomfield, A.R.A., Detmar Blow, Edward Boehmer, G. E. Bond, Alderman Sir T. Vansittart Bowater, C. W. Brooks, F. S. Brown, George T. Brown, John J. Burnet, A.R.S.A., James T. Cackett, Rhodes Calvert, Vere Calvert, Sydney H. Caslon, Christian Christensen, F. Dare Clapham, Max Clarke, S. D. Clippingdale, M.D., Thomas E. Collcutt (Past President), John Collings, Howard Colls, A. S. Cope, A.R.A., Alfred W. S. Cross, Arthur G. Cross, E. Guy Dawber, Rudolf Dircks, R. S. Dods, C. Fitzroy Doll, David G. Driver, F. Eiloart, Frederick R. Farrow, T. Phillips Figgis, William Flockhart, Frank Fox, Arthur Franklin, Percival M. Fraser, Edward Gabriel, Matt Garbutt, Alan George, J. Melton Gibbs, James S. Gibson (Vice-President), G. L. Gomme, F.S.A., Montague Goodall, Alexander Graham, J. Braidwood Gray, Edward Greenop, Edwin T. Hall (Vice-President), Stanley Hamp, F. H. A. Hardcastle, Henry T. Hare, Ewen Harper, W. H. Harrison, Edward Haslehurst, Charles Heathcote, George T. Hine, George Hornblower, George Hubbard, F.S.A., A. A. Hudson, C. E. Hutchinson, Edward B. I'Anson, G. Thrale Jell, Harry Osborn Jenkyn, Joseph Jennins, J. J. Joass, J. Keeble, Otto Kyllmann, P. Ogden Lawrence, K.C., W. H. Lever, M.P., W. J. Locke, T. H. Loveless, Edwin L. Lutyens, J. Y. W. MacAlister, F.S.A., Mervyn Macartney, F.S.A., Bertram McKennal, A.R.A., Herbert C. Marshall, E. Vernor Miles, Professor Gerald Moira, H. Percy Monckton, H. Greville Montgomery, M.P., Albert W. Moore, Alan E. Munby, John Murray, G. Ernest Nield, George Northover, Paul Ogden, C. Stanley Peach, Captain Walter Peake, H. A. Pelly, S. Perkins Pick, S. Wilfred Pike, William A. Pite, Horace Porter, W. E. B. Priestley, M.P., Charles H. Read, LL.D., Professor C. H. Reilly, F. G. Rice, W. E. Riley, Percy Robinson, William Robinson, Reginald St. A. Roumieu, Ernest Runtz, E. Monro Runtz, W. Howard Seth-Smith, George Sherrin, Frank Short, A.R.A., Gilbert M. Simpson, Graham Simpson, F.R.C.S., John W. Simpson (Vice-President), John Slater, J. Osborne Smith, Lewis Solomon, S. A. Stanger, H. Heathcote Statham, Alexander R. Stenning, Frederick J. Stevenson, Augustus W. Tanner, Chas. Tanner, Henry Tanner, jun., W. J. Tapper, Herbert G. Tayler, A. G. Temple, Sir Brumwell Thomas, Hamo Thornycroft, R.A., George Traill, Percy B. Tubbs, Frederick Wallen, W. F. Wallis, W. H. Warner, Dr. R. J. Waugh, Thomas B. Whinney, W. Henry White, Frank W. Wills, A. Needham Wilson, George E. Withers, William Woodward, Percy S. Worthington, Alfred B. Yeates, Clyde Young, Morgan H. Young, and Iân MacAlister, Secretary.

The loyal toasts of "The King, the Queen, the Prince and Princess of Wales, and other members of the Royal Family" having been passed with musical honours,

Mr. JOHN W. SIMPSON submitted "The Houses of Parliament," remarking that without that security and peace which the wise and statesmanlike measures of the Legislature afforded to architects there could be no continuity or advance in the art which they practised. As artists they remained outside the strife of legislative wars, though they were sympathetic with the political troubles of others. Perhaps it was for that reason that the architect was politically rather a peculiar study. A Parliamentary scheme for improvement in building would find him in the ranks of the advanced revolutionary Radical, and yet any proposal for the restoration or reconstruction of an ancient monument would be opposed by the architect, thus proving him to be a staunch Conservative.

Sir CHARLES MCLAREN, M.P., in response to the toast, said the House of Commons was constantly voting large sums of money to be expended under the auspices of architects, though he fancied the lower House was more distinguished as an enemy to architecture than a friend. Its history showed that it had done more for the pulling down of ancient monuments than the preservation of them. The House of Commons, he said, was always ready to vote money for architectural and artistic purposes, and he suggested that it was the Treasury that should be blamed for the mean grants given towards their realisation.

Professor BLOMFIELD proposed the next toast, "Art, Science and Literature." He thought they might take it for granted that all architects worthy of the name were artists in intention. He had read recently in the *Times* that the status of architecture in England was higher than it had ever been since the eighteenth century. That was a high compliment to architects, though he believed that if they kept their eyes open they would find excellent work was being done in London and all over the country by men whose full reputation had not yet been reached. In spite of that he was afraid that architecture at the present moment did not receive the recognition in England which it deserved, and he asked who was responsible. He did not think the public were to blame—they had a very excellent public; he believed it was the gentlemen behind the public—the critics. There were, he was glad to say, critics of knowledge and discrimination, who handled their art with the utmost intelligence, but unhappily there were other critics or writers hostile to their art. Lastly, there were writers who absolutely ignored the existence of architects, and who did not recognise the fact that there were a great number of very able men who were devoting themselves to the practice of architecture. In the past architecture was a very great art and occupied a great place among the arts, and it ought to occupy that place again. With regard to the sister arts of painting and sculpture, he felt he need not say very much before such an assembly, because all present loved those arts and found in them a source of most delectable pleasure. Alluding to sculpture, he spoke of the magnificent technique, the fine lines and high personal qualities of Mr. Brock's memorial to the late Queen Victoria, and described it as a distinct gain to London.

Sir LAWRENCE ALMA-TADEMA, in responding for painting, said there was some difficulty in explaining what the word "art" meant. Perhaps sometimes by means of an emblem one could suggest a little what art might be. He remembered the King of Sweden once describing art as the flower of the tree of life, and the simile was a good one, for life would be like a tree in winter if there was no such flower as art to cherish and make men happy.

Digitized by Google

Mr. Henry Morris, President of the Royal College of Surgeons, replied for science, and Mr. W. J. Locke for literature.

Sir Melvill Beachcroft proposed "The Royal Institute of British Architects," and referred to the improvements made in London since the London County Council came into existence twenty-one years ago, and suggested that the City was rapidly becoming worthy of being the capital of the Empire.

The President, in replying to the toast, said:—

We celebrate to-day our seventy-sixth anniversary, and it is seventy-two years since, under its then president, Earl de Grey, the Institute of British Architects received its Royal Charter. Since our gathering last year, the most important incident is that his Majesty has been pleased to grant us the new or supplemental charter for which we applied. This enables us to make rules for the better ordering of our house, for the regulation of ourselves, and we hope for the benefit of the community. The said revision of the charter and by-laws is the result of a movement that stirred, if it did not divide, our camp. Architects, especially those in the provinces, found that work which should come to them too often went to auctioneers and others who ventured to include architecture in their sphere of usefulness. In our enlightened metropolis some will get not only their groceries, but architecture and decorations from the Army and Navy Stores, from their upholsterer or from like professors of our art. This is a trouble, but it must be met by keeping our own work at a high level, and by a growing perception of what is good on the part of the public. To have all architects licensed or registered has been proposed, though this would not prevent the employment of outsiders; we should also have to admit all sorts and conditions of those in practice. We prefer to insist that in future all shall enter through the schools, obtaining their diploma or certificate, which will distinguish the architect from the quack, and we look for further legislation to accentuate the difference. The change will come gradually by a wise organisation of our training schools, bringing all into line, and demanding that a certain standard of efficiency shall be attained by those who would enter our guild. This will be the preparation for Associateship, and our Fellows will be chosen only from those who have passed the schools with a sound knowledge of the constructive art; thus ensuring the public against ignorance and incompetence. A board of examiners cannot guarantee that a man is an artist.

To meet the exigencies of the hour the charter makes provision for a new class to be styled Licentiates, under which head we hope to receive into the Institute the large number of practising architects who have outgrown the days of schooling and examinations. Till of late the Institute has not been an educational body, having helped only by the awarding of prizes and travelling scholarships. A distinct advance has been made in the system of training, and our young men will start with a better equipment than their seniors enjoyed; we hope they will do better work. Students of ability are coming to the front every year and carrying away our scholarships. It would be a grand thing for these promising men, and a public gain, if some of these had an opportunity of carrying their studies further, in a higher school, acquiring a knowledge of what is really great in art. A special school has been suggested for these diploma men, among whom a distinctive prize, a "Prix de Rome," would be awarded. We feel that Englishmen may have their "School of Rome" and be under the influence of the noblest monuments, as well as Frenchmen, Germans, and Americans, who have that advantage. A British School of Rome exists, and with its members we have been conferring; it is doing admirable work. It consists of archæologists, savants, professors and men of letters, and they cordially invite us to join them in any project we may have. Their present arrangements would not accommodate us or meet the requirements we have formulated for our architectural school, but an amplification of the present institution would please us better than to start a separate venture. Our committee, which has been considering this scheme, will shortly have a definite proposal to bring forward. We should like to think that in time painters, sculptors and architects will be comrades in such a school. Ways and means are always an important feature in any enterprise. We have funds which may fairly be employed in this educational scheme, which is one that may appeal to generous donors who are interested in the growth of art among us. Hitherto the general public has declined to know anything about architecture as a fine art; a good building has not always been appreciated, nor a bad building always found out. There are indications of a growing knowledge in the matter, and of a higher criticism, and this I am sure will be responded to by ourselves. Buildings that may be classed under the head of architecture remain much in the minority, but if taste improves we may find even the speculator giving us honest buildings, on simple lines, instead of "jerry" work with foolish ornament. As a rule the community gets what it wants; our hope is that it will learn to want the best. For the execution of work we have skilled craftsmen, and our admirably furnished technical schools will increase knowledge and power. These schools we value most as providing evening classes for the practical mechanic; they are not a substitute for the good system of apprenticeship. There is with the schools always a danger that a boy gaining a useful training in colour, in modelling or drawing (most helpful to him in his craft) will think that he must, with this smattering, become an art student, paint pictures, produce statues, or become an architect, thus swelling the ranks of the useless unemployed. A good mechanic is a nobler object than a bad architect. It is disturbing to think what will be the future of our many promising men who are starting with every advantage and with a sound knowledge of their calling; there seems hardly work enough to go round. We have fallen upon bad times and, I believe, with few exceptions, architects' offices and builders' shops are very quiet. Those who should be building houses either have not the money or are spending it on motor-cars or on Old Masters. We are waiting for the world to mend. Fortunately, public works and municipal works are not feeling a similar check. We are only just realising that our cities are not all that they might be. We have beautiful buildings but they occupy positions, as if by accident rather than design, for the most part hemmed in, often by mean surroundings. We owe much to our Government for the "Town Planning" Bill, by which in time we hope to gain healthy and open spaces, dignified approaches, and the beauty that comes of a well-studied "lay-out," with architectural treatment. Changes must come by degrees to the already crowded cities, but when new ground is broken and new suburbs are taken in hand, builders will conform to some well-studied plan. We owe much to Mr. Henry Lever, our guest to-night, for his generous endowment of a school of architects, for the special study of town planning. In the interests of art we architects must be willing to sink some of our individuality for the sake of continuity and harmony, symmetry and balance. We have been too anxious, on each narrow frontage, to stamp our own mark. Our personal originality is not a matter of importance, requiring a public memorial. A great thing is to be prepared beforehand for future developments, and we are formulating, for general guidance, rules that should be observed, and which would generally apply to such scheming. The possibilities of our own city are being studied; while our allied societies are considering their own several cities and towns with a view to their best development, they will then be ready with advice when changes are required. The Bill of Mr. John Burns gives us the opportunity of making representations, criticisms, or suggestions before any new scheme is sanctioned, and we hope to use a helpful influence. We have made a good fight from time to time in the interests of some valued building or monument, to save it from destruction or from being "Grimthorped." We have sometimes failed in our immediate object, but good has been done. We have shown the honest Philistine that there is a second way of viewing things, and that to many the intrinsic beauty of a subject is a real possession that must not be carelessly swept away. The æsthetic side has been too often overlooked where changes have been made for convenience and economy, when a noble conception might have been realised. Curiously, the American architects in Conference have just made inquiry of us as to the British rules or regulations for securing architectural treatment or style. With regret we replied that every man is a law to himself, no regulations deal with the quality of beauty; it is not taken into account. We are thankful for the appointment of the Royal Commission for the Preservation of Ancient Monuments, which is under the chairmanship of our distinguished guest Lord Burghclere, and on the council of which is our vice-president, Mr. Leonard Stokes, while Mr. Forsyth is vigilant on the Council of the National Trust for Places of Historic Interest. We have a Building Act, which we are all supposed to know intimately. It was simple once, but it has become overlaid with laws till it is now as big as the catalogue of the British Museum. It is being revised and enlarged, and it proposes to spare architects' responsibility for their work. It will define for us all details of construction for the insides of our steel-framed buildings, as well as for the party walls and front walls

Digitized by Google

which should be under its regulation. The work of the architect's office will be transferred to the multitudinous, overworked clerks of a public office; causing delays that will be disastrous to building operations. We have urged the objections to such a drastic change and I believe our arguments will be graciously considered in Committee. Our vice-president, Mr. Edwin T. Hall, has been indefatigable in his efforts in this cause. An Act would be simpler that defined the things that must not be done in building. Steps are now being taken to secure the protection of "copyright" to the works of the architect, equally with those of the painter, sculptor, and literary man. At the various international conferences this has been insisted on, the British section only showing indifference to the matter. Now, at the representation of our Institute, our Foreign Office has practically accepted the principle, and Mr. Belcher and Mr. Simpson are only pleading for Parliamentary ratification of the Berne Convention, which included architecture with other arts. Plagiarism and the borrowing of ideas will perhaps remain as general as at present, but our drawings and studies will be our own, as a painter's rough sketches are his own, although he may sell the picture for which they were made. This ownership will be clearly established in face of sundry legal decisions in the past. The client pays for the house we build him, and not for the processes we may employ in the making of it. A good client lately showed me with pride a group of cottages that seemed familiar, though in strange surroundings. "These," he said, "are copied from those you did for me on the other side of the park," and I had not the heart to tell him his was an act of piracy. The copyright for which we ask will secure to us our documents as well as other privileges of which we have doubtful possession at present. Last year we had the honour of conferring our Royal Gold Medal upon Monsieur Honoré Daumet, who was also our guest. This year it has been decided with his Majesty's approval, that the medal be given to Dr. Arthur J. Evans, in recognition of his discoveries in Crete, a priceless addition to our knowledge of the past. He has devoted his life and means to the great work of exploration. Dr. Evans would be with us now but that he is burrowing below ground in Crete. He comes to us in November to tell his story, and to receive the decoration. Our Royal Institute may be reported as in a healthy and prosperous condition. Our roll of 2,300 members is larger than heretofore. We have our seventeen allied societies in the United Kingdom, three in South Africa, one in Canada, and one in Australia. We have been consulted on various matters by those in office, and we have an increasing influence which I hope has been used for the general good. On behalf of the Institute I can only thank you for the way in which you have honoured the toast.

Sir ASTON WEBB submitted the toast of "The Guests," Mr. W. H. Lever, M.P., responded, and at a late hour the company dispersed.

AUSTIN FRIARS CHURCH.*

IN A.D. 1252, having obtained authority from Pope Innocent IV., the Eremite monks of the order of St. Augustine settled in London, and by the bounty of Humphrey de Bohun, Earl of Hereford and Essex, commenced their work in the heart of the town on the spot now occupied by the Austin Friars Church and surrounding property.

Their rules forbade them to hold property, except presumably the land and buildings which they occupied and in which they worshipped. They cultivated learning and fulfilled the useful function of schoolmasters. They were habited with black gowns with a white habit, with cloth hood and black leathern belt. They were not a numerous settlement, and possessed a good reputation for character and discipline.

VIEW OF INTERIOR OF AUSTIN FRIARS CHURCH, LOOKING EAST.

The outline of the old arch at the intersection of the nave and transept is clearly visible above the organ, also the outline of the east window, probably inserted when the Dutch Community began to worship therein and blocked when the organ was placed there.

In A.D. 1354 the grandson of the original benefactor rebuilt the monastery. The church seems to have been a very spacious structure, as the nave and aisles, which are the only portions remaining to this day, measure 153 feet in length by nearly 100 feet in breadth, so that the transepts and sanctuary must have extended a long way eastwards from the present end.

Stow tells us that the roof was high pitched with a barrel ceiling, and the crossing was surmounted by a very graceful spire or steeple, which was the admiration of the citizens, who vehemently protested against its destruction by the Marquis of Winchester after the dissolution of the monasteries.

The original roof over the present building existed up to fifty years ago, when a disastrous fire took place, entirely destroying it, and it is a matter of great regret that its form was not reproduced on the old lines at the restoration following.

It is probable that the church, with its monastic buildings and garden, covered in all an acre or more of ground. The

* Part of a paper read at a meeting of the Upper Norwood Athenæum by Mr. Frederick Higgs.

Digitized by Google

old map of London, made in the sixteenth century, shows a very large space of ground on the side and back of the church building.

At the time of the suppression in Henry VIII.'s reign the church was very rich in monuments, burial within its precincts being much sought after and a high fee for the privilege was obtained. Besides the founder and his grandson, the great Hubert de Burgh, Earl of Kent, rested there; also several of the nobility who suffered death from time to time by execution on Tower Hill and Cheapside. Many others obtained sepulture by purchase.

One writer mentions thirty-six visible monumental slabs, seventeen with one or more figures and sixteen with shields or inscriptions. To-day in the nave alone the slabs on which brasses were originally placed are very numerous.

At the dissolution in 1534 there were only thirteen friars in residence, all of whom received pensions or other emoluments. The property was granted by the King partly or successively to Wriothesley and Sir Richard Rich, but passed eventually to the Earl of Wiltshire, afterwards Earl of Winchester, except the nave and transepts of the priory church.

This nobleman cleared out all the monuments, raising money on them, and pulled down the transepts, chancel, spire and the monastic buildings, selling part of the materials and using the remainder to erect the house known as Winchester House for his sole use and benefit.

Stow quaintly writes under date 1603 as to this:—"The goodly steeple and the east part of the church have lately been taken down and houses for one man's commodity raised in place thereof, whereby London has lost a goodly ornament, and times hereafter may the more talk of it." He evidently dared not say much at that time.

At this period a number of well-to-do Dutch refugees had come to reside in London and other parts of the country through the religious persecutions prevalent at that time in the Netherlands, and through high-placed influence they obtained a grant from Edward VI. of the remnants of the church as a meeting place where they could worship God according to the light that was in them without let or hindrance. They put it into repair, and in the process reglazed the windows. There is a small fragment of this glazing in the south-eastern aisle window, having thereon the inscription "Jesus Temple," which was the name they loved to give it. The Bishop of London was appointed special guardian of their liberties, and arbitrator in all questions arising out of their fellowship.

On the ascension of Mary Tudor the Dutch refugees were all sent back to their own land, and the church was unused; but when Elizabeth succeeded they came back and resumed, with their former trades and occupations, the use of the old church building for worshipping God in, which use has been continued uninterruptedly down to the present time.

There is in the strong-room an unique collection of original letters and documents relating to the Dutch Church and its affairs from its foundation onwards, among others being one from William Prince of Orange and Nassau, dated 1597, appealing to his fellow-countrymen to aid in his wars against Spain; also one from that great painter Albert Dürer. The registers date, baptisms from 1563 and burials from 1602. The communion plate is 1602.

In the vestry is a Jacobean pastor's chair almost as old, four excellent Chippendale chairs, and a grandfather clock dated 1679.

The community is well-to-do, maintains a pastor—owing to whose kind consent we have been able to inspect their ancient building—do a great deal of good in the way of charity to needy Hollanders in our city, and maintains almshouses at Charlton. Long may they live and flourish! The worthy and well-informed verger, Mr. Rus, is quite delighted to show his building to visitors who are interested in the history and work of his community and of the grand fane in which they worship.

There are some interesting features in the old building worthy of notice. Like the Temple Church, the arcade columns are exceedingly slender, but show no signs of inadequacy to the work laid upon them. The exterior walls are built of squared block chalk with an external face of Kentish rag. The whole building leans over southwards more than 12 inches. This list is tested from time to time, but there is no sign of movement, and it is probable that the deviation took place centuries ago. There is a half altar stone, now deposited in the north aisle, which probably belonged to one of the chapels of the monastery previous to 1534. Besides the floor slabs before referred to there is otherwise little of note.

ILLUSTRATIONS.

PROPOSED GARRISON CHURCH, KHARTOUM.

WE reproduce the water-colour perspective of the above building, which is exhibited in this year's Royal Academy. It is proposed to build the above church for the use of the British garrison stationed in Khartoum on a site adjoining the barracks on the south bank of the Blue Nile. It is designed to accommodate a congregation of 700 at an estimated cost of £E.10,000. The materials are local red brick with bands and dressings of white sandstone from the Gebel Auli quarries, a few miles up the White Nile, and the roof of red Marseilles tiles. To English eyes, perhaps, the building is not particularly ecclesiastical in style, but in a country where craftsmen are unknown and skilled labour at a premium it is necessary to obtain effect by simple means. Coolness being one of the first essentials in a building of this character for the tropics, an arcade and wide projecting eaves have been introduced in order to shade the external walls as far as possible. The church was designed by Mr. O. Beeston Hatchard, town architect, Khartoum.

ELEVENTH-CENTURY FRESCO IN THE CHURCH OF ST. EDMUND, KING AND MARTYR, KINGSDOWN, KENT.

CHURCH OF ST. EDMUND, KING AND MARTYR, KINGSDOWN, KENT.—INTERIOR.

THESE plates are in illustration of our article (p. 346) on the "Discovery of an Eleventh-century Fresco." The photographs from which the illustrations are prepared were taken by Mr. James W. Borland, an amateur photographer on our staff.

MAIDENHEAD SECONDARY SCHOOL FOR BOYS.

THE site for this building presented exceptional difficulty as regards levels, as many pockets existed where sand had been excavated for trading purposes. The conditions required accommodation for 150 scholars, with possible expansion, and the central assembly hall to be used for a dining-room, a science-room, library, &c., and a small house for the caretaker. The grounds were to be laid out with special provision for four fives courts, cricket and hockey grounds, reserved garden for botanical specimens, pavilion, &c. The cost was not to exceed 5,000*l*. The design here given was submitted in competition by Messrs. Sheppard & Bullock, of 43 Chancery Lane, W.C., and is treated in a simple manner. It was intended that the elevations should be faced with local red bricks, relieved by Box-ground stone dressings, and the roofs covered with Broseley tiles. The windows of all classrooms are carried up to the ceiling level, all double hung, some having the upper portion hung on centres for ventilation. The aspect of the principal classrooms is south-east.

THE illustration given this week of Queen's College is in completion of those in previous issues, with the historical account of the College by the Provost, Dr. Magrath.

OXFORD COLLEGE SERIES, THE BODLEIAN LIBRARY.

An account of the Bodleian Library is given on p. 355.

Cambridgeshire as a field for archæological research has not in the past been worked as fully as might be, and the Cambridge Antiquarian Society is making a serious effort towards carrying out the systematic excavation of the numerous unexplored sites within the county. Southern Cambridgeshire and the Isle of Ely are promising fields for excavation. Newmarket Heath with its tumuli, besides others in the county, would probably amply reward exploration. Roman remains may be expected to be found in plenty in the southern part of Cambridgeshire, which was probably thickly peopled by Romans and Romanised Britons, whilst Cottenham is a particularly promising field.

THE INCORPORATED CHURCH BUILDING SOCIETY.

THE annual general court of the above Society was held in the Church House, Westminster, on Friday last, when the chair was taken by the Archbishop of Canterbury. Mr. Joseph Monday, the secretary, presented the ninety-first annual report. The general summary of the operations of the Society since its formation in 1818 showed that the total number of applications for aid was 11,120. The grants made numbered 9,160—viz. in aid of the erection of 2,565 additional churches and chapels, and of rebuilding, enlarging or otherwise improving the accommodation in 6,595 existing churches and chapels. By these means more than two million additional seats were proposed to be obtained, of which about three-fourths were to be set apart for the free use of the parishioners. The amount given by the Society towards these works was 926,851*l*. The estimated amount of further expenditure on the part of the public is 16,978,453*l*.

In the course of the report it is stated that:—

In asking for the Society increased financial support there is need to ask also for a more intelligent interest in the Society's architectural mission; that a right mind and a right aim should control the expenditure of funds upon all our new churches and specially upon those of our expanding suburbs. Never so much as in those dull districts where there is so little of the ideal do we need a standard of beauty and a source of pride. It matters not whether a building be Gothic or Classic in spirit, provided it be good of its kind and the needs of a district and its worshippers are well considered and met. The more difficult it is to raise the requisite funds the more care should be exercised in the spending of them, and the Society has from time to time found it needful to reiterate the view that mere cheapness is not to be commended in the erection of a house of God, which should be devised and destined to endure for centuries. It is no less important to reaffirm that the essential qualities of convenient planning, good proportion, and the dignity and refinement inherent in well-conceived church architecture, even of the simplest character, are much more dependent upon the taste and skill of the scholarly and competent architect than upon a large and often unnecessary outlay disposed by tasteless or comparatively unskilled hands. The inheritance of religious architecture in the country, especially in the Anglican communion, is a precious possession, and the Society is ever ready to encourage and assist the promoters and patrons generally of church building to spend the funds raised for this purpose in such a manner that our great inheritance, and all it means for the Church and nation, shall in no sense be impaired.

In this connection the Society cannot too strongly impress upon those in whose special charge our ancient fabrics are vested that they are responsible for what cannot be recreated, cannot be bought, and when once lost or injured cannot be recovered.

While the reasonable adaptation of ancient and historic buildings to modern needs is not in itself to be objected to, and is even sometimes essential to preserve such a building in active use as well as from decay, no work should be undertaken destructive of its hallowed or historic character, and nothing should be done without seeking the advice of a professional man with a wide experience in this class of work, which is the most difficult that an architect can undertake. On no account should the jobbing builder be allowed a free hand upon an ancient church. . . . The committee take this opportunity of thanking the members of the committee of honorary consulting architects, who give their services so ungrudgingly to the Society by examining with the greatest care the designs submitted to them at their monthly meetings. By the resignation through ill-health of Mr. B. Ingelow and by the death of Mr. W. M. Fawcett, M.A., F.S.A., the Society has lost the services of two distinguished church architects. While deeply regretting the loss of these valued members, the committee cordially welcome Sir Charles A. Nicholson, Bart., and Mr. C. S. Spooner, who have been appointed to fill the vacancies thus created.

The full list of honorary consulting architects now is:—Mr. W. H. Bidlake, M.A., Mr. W. D. Caröe, M.A., Mr. C. Hodgson Fowler, Mr. C. H. M. Mileham, Mr. Temple Moore, Sir C. A. Nicholson, Bart., Mr. E. S. Prior, Mr. G. H. F. Prynne, Mr. J. Oldrid Scott, Mr. R. Norman Shaw, R.A., Mr. C. S. Spooner, Mr. E. P. Warren, Sir Aston Webb, R.A.

The committee desire to call attention to the fact that during the past year the "Occasional Notes on Church Furniture and Arrangement" have been reprinted and published in pamphlet form. These articles were originally contributed to the Society's quarterly magazine, the *Church Builder*, by the eminent architect and antiquary, the late Mr. J. T. Micklethwaite, F.S.A., who was for many years a member of the committee of honorary consulting architects of the Society and surveyor to Westminster Abbey. The committee strongly urge that all lovers of church architecture should carefully study these valuable articles and do all in their power to ensure their wide circulation. If this be done, the committee feel that the high standard in church building which the Society fosters, and which Mr. Micklethwaite did so much to promote, will be maintained. A copy will be sent post free for 7½*d*. on application to the secretary of the Society.

Mr. Edward Warren, F.S.A., in moving the adoption of the report, spoke as follows:—I wish first of all, on behalf of my colleagues, to thank the committee for their kind expressions in regard to the labours of the honorary consulting architects, and to join in the expression of sincere regret for the loss of two of its respected and distinguished members by the resignation of Mr. Ingelow and the death of Mr. Fawcett, as also in the cordial welcome to our ranks of their successors, Sir Charles Nicholson and Mr. Spooner.

This Society is, of course, as all such associations must be, urgently in need of further and continued contributions.

It is as representing a class of contributors who are able to offer only the contribution of such knowledge and skill in architecture as they possess and have attained—not without pain—and as a constant participator in the burthen of study and criticism imposed upon the consulting committee, that I venture to offer a few observations prompted by the share in that task which I have been privileged to bear. Amongst the very large number of plans representing schemes for new churches or the enlargement or alteration of existing ones, old or modern, the percentage which we find it possible (always to our very great pleasure) to approve absolutely is small, but I think I may fairly say that we do find an increasing tendency to accept and obey the main constructional requirements of our Society and to endorse the spirit as well as the letter of those instructions. The number, however, is still large which is sent to us showing not only ignorance of the Society's requirements, but of the ordinary practical needs of a church, and a sad lack of perception of the befitting attributes in honest soundness of structure, simple excellence of materials and quiet dignity of effect.

It is frequently painful to us to have to consider schemes for the building of churches whose submission to our judgment is in itself a proof of slender financial resources, which seem to aim rather at a certain Cockney splendour than at the sober and restrained adequacy which is barely attainable within the limits of the possible expenditure. It is perhaps more than ever painful, to minds trained in the study and love of ancient architecture and attuned to its serene sincerities, to have to sit in judgment upon plans, generally well meant, which nevertheless portend the woeful mishandling of some quiet, delightful, old country church, to which time and weather have imparted an irreplaceable beauty, and in which the direct and simple alterations and naive additions of successive generations have furnished, to all who can read them, instructive pages in the history of our Church and our country. There is often, alas! evidence of a misguided desire to smarten, to Cocknify, or, if I may use the expression, to "suburbanise" the old gray churches of our quiet countrysides by the ruthless application of smart and imitative workmanship in cheap materials, or by the substitution of the unsympathetic and ready-made accessories of the ecclesiastical tradesman for the sober and humble time-worn old fittings and furnishings of our simple-minded predecessors. It is bad enough that a brand new building dedicated to the worship of God should present the thin, hard lines, the cheap symbolism, the thoughtless, joyless travesties of ancient and beautiful things, but it is worse—indeed, to many of us it is heartrending—to witness the perversion of a quiet and lovable old church to the common standard of modern ecclesiastical smartness, with its crudities of encaustic tiling, its horrible machine-made lacquered brasswork, its "reach me down" reredos, pulpits and lecterns, and the pervasive treacly vulgarity of varnished pitch pine.

The brand new must be brand new, of course, and there is nothing wrong in newness. It has, indeed, a distinctive charm of its own, and when a new building is thoughtfully and skilfully planned; proportionate, dignified, substantial and strong, it is a thing to be glad of, wholesome all round, the honest outcome of an honest purpose. But where, as is often the case, it is necessary to add to an ancient church—a thing which I believe you will agree with me should only

Digitized by Google

be done under the stress of sheer necessity—I feel that the inevitable newness of the addition requires, in order to do no hurt to the old structure, more care and thought, perhaps more skill, than unhampered new building on a new site; and I think it is generally only on simple directness of purpose and frank declaration of the addition as such—in the use of materials, of local origin where possible, or at any rate of kindred nature and assimilable in time to those of the old building, as well as in avoidance of sham antiquation or mere detail-copying of the original building—that harm is avoidable. See that your walls are comfortably thick, a little over the minimum requirements of this Society wherever possible; that your piers and arches are strong and simple, and that your roof timbers and roof covering are substantial and sound. Forego all adornment, leave tracery out of windows, have chairs instead of pews, avoid all cusping and crocketting, carving or ornament of any kind, but have the building sound and solid, and above all seek sincerity of structure rather than ingenuity. Such would be my exhortation to clergy and architects alike.

In new churches I think my brethren of the consultative committee will agree with me that in most cases submitted to us the elimination of mere ornament would usually make possible better constructed, thicker walled and more substantial buildings, and often the provision of more ample space. I am struck by the, as I think, extremely regrettable tendency so generally displayed to fit a church closely to the mere seating accommodation demanded by local conditions, allowing for unseated floor spaces the merest exiguity of passage ways. This is very different on the Continent, where a much greater sense of the dignity of space appears to obtain in the planning of churches. There is sheer satisfaction to the eyes and indeed actual beauty in the proportionate distribution of enclosed space, and while perhaps it may not be possible for us to increase our minimum requirements in that direction, I suggest that we might accompany their statement in our rules by a suggestion as to the extreme desirability of more ample spaces.

In conclusion, and again, I believe that on this head I may safely speak for the committee of consulting architects. I feel that our work would be more useful, and the influence of this Society upon ecclesiastical architecture greatly strengthened and improved, if more power and wider discretion were given us in recommending for grants, in respect to the architectural character of designs submitted to us, as well as in regard to mere structural sufficiency. Might it not, for instance, be possible to have recognised classes or categories to which, in our criticisms, we could assign the various plans, in accordance with their general merits, and which might influence the executive committee in its decision as to grants? We should like to be able to feel that our grants conveyed æsthetic as well as merely practical approval, and that, if possible, a sort of bonus were bestowed upon unusually excellent and harmonious designs. If it is not possible, in view of our unfortunately narrow financial limitations, to make an increased money award to architectural excellence, we might at least devise some system of "starring," so to speak, designs especially approved by the honorary consulting architects. In this way it would soon get to be felt that where the plans for a new church or for an addition were starred by the Incorporated Church Building Society, the promoters would have leverage for an especial appeal, the value of our grant would be morally increased, a deserving architect would receive express recognition, and your consulting architects would have the gratification of conveying especial approval, and of feeling that the Society was doing its best to secure beauty and fitness of design as well as soundness of structure and convenience of plan. It is generally admitted that a marked and most hopeful advance has been made within the last few years in secular building, but, as my colleague Mr. Prior so ably pointed out to you when addressing the annual general court a year or two ago, the building of churches has scarcely shown corresponding advance—a sad admission, as we shall all feel.

Time was when the Church was the high centre of all artistic activities, the inspiring source of artistry in every craft. Time was when her buildings were the supreme emotional expression of the creative fervour of the land. We can hardly hope, I fear, in this age, when the building instinct inherent in man is dulled by the myriad competing interests of our complex life, to restore that state of things, but we can, and this Society more potently perhaps than any other organisation, bear our testimony to the need for dignity and beauty in the buildings of the Church, and which, as the report so justly signifies, is especially great in these days amidst the mean and sordid surroundings of industrial neighbourhoods, where, if anywhere, an approach to the ideal of beauty, an oasis of refreshment to tired minds and monotonous lives, should be found in the parish church.

THE BRITISH FIRE PREVENTION COMMITTEE.

THE British Fire Prevention Committee, which was founded on the occasion of the great Cripplegate fire of 1897 and which was incorporated in 1899, is celebrating the tenth anniversary of its incorporation this month on the 24th and 25th inst., when a number of distinguished visitors will be attending its meetings, including several from abroad.

The committee's primary object during the last ten years has been to deal with the protection of life and property from fire by the adoption of preventive measures, and it has certainly favourably influenced the reduction of the possibilities of fire and spread of fire during that period, not only in the metropolis but throughout the empire.

The greater knowledge of building materials and appliances obtained by scientific independent tests at the committee's testing station has done much to obtain a better understanding of the value and also the limitations of different methods of construction and equipment, whilst considerable influence has also been exerted by the committee in guiding building and fire service legislation in directions where it is most effective to prevent loss of life and loss of property. Probably the most notable event in the committee's life was the large International Fire Prevention Congress of 1903, and the arrangement of the technical exhibits at the Fire Exhibition that was held on that occasion at Earl's Court. No less than 800 delegates attended the Congress, including over 200 from abroad. The reports issued by the committee to its members number 140, and comprise a most comprehensive library on the subject of fire prevention. Special publications have also been issued from time to time dealing with the visits of special commissions formed by the committee to study matters of fire prevention on the Continent. Popular booklets have also been issued, such as children's fables warning children not to play with fire. Among the original founders now deceased probably the best known were the late Mr. Thomas Blashill, F.R.I.B.A. (late Superintending Architect to the London County Council), Mr. Arthur Cates (Crown Surveyor), and Mr. James Sheppard (Insurance Surveyor). Of the founders who have held office on the Executive from the time of its incorporation to the present time should be mentioned Mr. Edwin O. Sachs, F.R.S.Ed. (Chairman), Mr. Ellis Marsland (Hon. Secretary), and Mr. Max Clarke, F.R.I.B.A. Other members who have been doing active service for many years are Messrs. J. Herbert Dyer and Horace Folker (Vice-Presidents of the National Fire Brigades' Union), and Mr. Percy Collins, J.P. Quite a number of the chief technical officers of the Government Departments concerned have regularly supported the committee, notable among them being Sir William Preece, K.C.B., Sir Boverton Redwood, F.R.S.Ed., Sir Henry Tanner, I.S.O., Sir John Taylor, K.C.B., Sir James Williamson, C.B., and Major O'Meara.

To give some idea of the extent of the committee's field of influence, it should be mentioned that one of its sub-committees in New Zealand alone counts twenty-five members. Its list of honorary foreign members and active correspondents includes several distinguished names, not least among these being those of the well-known police chief of Paris, Monsieur Lepine, and the head of the Russian Fire Service, Prince Alexander Lvoff, both of whom have been over to see the committee's work. The objects tested by the committee since its formation number 160 to the end of last year, and it should be understood that the investigation into any one object sometimes requires as many as twenty or thirty testing operations. Notable tests have been those with large reinforced concrete floors, a series of fifty fire-resisting doors, fire resisting glazing, and latterly also with safety devices.

Perhaps a final feature that claims remark is that the whole of the funds required for the establishment of the Committee's Testing Station and the execution of its work have been raised voluntarily, that over 20,000*l.* have been expended in ten years on the work of the committee, and that the whole of the services rendered by the committee and their officers are rendered voluntarily, members, as a matter of fact, even bearing all their own out of pocket expenses.

It is customary to decry the research work done in the United Kingdom as compared with the research work done elsewhere with the aid of Government grants and subsidies, but the British Fire Prevention Committee's Testing Station

Digitized by Google

has so far not been rivalled in any other country, although imitated in the United States, France, and Germany, with the aid of Government funds, and from the outset both the arrangements for investigations and the actual reports have not yet been surpassed anywhere.

BODLEIAN LIBRARY.*

THE first actual University Library at Oxford, and indeed the first of mediæval times, was commenced about 1367 in the north-east corner of St. Mary's Church, to accommodate the books collected and bequeathed by THOMAS COBHAM, Bishop of Worcester. In 1426 the University authorities embarked on the formation of an independent library, and in this they were greatly aided by Duke HUMPHREY of Gloucester, son of HENRY IV., a munificent patron of the new learning. Their efforts met with such success that twenty-two years later they informed him of the necessity for larger quarters and offered to make him founder. The new building was completed in 1480, and still forms the central portion of the great reading-room.

One of the early troubles, and it was one that endured through succeeding centuries, was in connection with the "lending department." Bishop COBHAM laid down that a scholar might have the loan of any book of which there was a duplicate copy, providing he left a pledge exceeding it in value. In course of years the amount of the pledges decreased as the value of the books increased, with the result that thefts became of scandalous frequency. It is related that one historian, who had been refused any further opportunities for abstraction, obtained a special licence from HENRY VIII. to take out any MSS. he might require. The annals contain constant references to the same dishonest practices which have been through all centuries the one weakness of bibliophiles. Indeed, it is hinted that Sir THOMAS BODLEY himself had on occasions of great temptation rather broad ideas as to meum and tuum.

In 1550 the Commissioners appointed under EDWARD VI. for the reformation of the University visited the library, full of that iconoclastic zeal that wrought such irreparable harm all over the country. All MSS. ornamented with illustrations or rubricated initials, whether missals or not, were destroyed or removed, as conveying Popish doctrines. The rest were left unprotected and found many strange uses. In 1555 the work of destruction was completed by the appointment of delegates to arrange for the sale of the shelves and stalls of the library.

It was four years after this disgraceful date that THOMAS BODLEY came to Magdalen College from Geneva University. In 1563 he was elected Fellow of Merton College, and held various offices until he went on the Continent at the age of thirty-two. He later made an unsuccessful attempt to get elected into Parliament, but achieved considerable reputation in the diplomatic world. Becoming tired of intrigues and jealousy he, to use his own often-quoted letter, "concluded at the last to set up my staff at the library door in Oxon, being thoroughly persuaded that in my solitude and surcease from the Commonwealth affairs I could not busy myself to better purpose than by reducing that place (which then in every part lay ruined and waste) to the publick use of students." Accordingly in 1597 he wrote to the Vice-Chancellor as follows:—"There hath bin heretofore a public library in Oxford, which is apparent by the room itself remaining, and by your statute records. I will take the charge and cost upon me to reduce it again to its former use." The offer was accepted, and various offers of help were received. Merton supplied the timber. In two years the beautiful roof which still shows BODLEY'S arms on the bosses was completed with other work. In 1600 BODLEY turned his attention to collecting books. He prepared a Register in which to record the names of all benefactors with their gifts. These two large volumes in vellum are one of the treasures of the Bodleian.

* See Illustration.

The first library-keeper was THOMAS JAMES, Fellow of New College, who signalised his appointment in 1601 by presenting over sixty printed volumes as well as MSS. There seems, however, to be some doubt as to whether he honestly got possession of the latter. Mr. JAMES was apparently a forceful character, for almost immediately after accepting the post he demanded that his salary of 5*l.* 13*s.* 4*d.* a quarter should be raised. It is unlikely that he was very successful, for sixty years later the occupant of the office received only 33*l.* 6*s.* 8*d.* a year. He also applied for permission to marry, despite the statute as to celibacy. Though BODLEY after long hesitation consented to grant an exception in his case, the rule of celibacy was rigidly enforced on all librarians for the next two hundred years.

Sir THOMAS BODLEY must have had the secret of making friends, for his appeal for books met with an instantaneous and generous response. The men of Devonshire were proud of the family's long connection with their county, and a local historian records "every man bethinks himself how by some good book or other he may be written in the scroll of benefactors." Some of the greatest treasures were given from episcopal palaces. By 1602 the volumes numbered over 2,000, and the library was formally opened by the Vice-Chancellor in that year in solemn procession. In 1605 King JAMES I. paid a lengthy visit to it, and showed more than the usual royal graciousness. He offered to present from all the libraries of all the royal palaces whatsoever precious and rare books the founder might care to carry away with him, and he promised that the grant should be made under seal, lest any hindrance should arise. Though this was duly carried out three months later, there seems to have been very little acquired. Nearly twenty years later JAMES presented to the Bodleian the folio edition of his "Works." It was taken to Oxford by a special deputation (the leader of which received a present of 20*l.* from the authorities), and was carried in state to the library by the Vice-Chancellor, with twenty-four doctors in their scarlet robes. The literary monarch was greatly flattered, more especially as "Cambridge had received them without extraordinary respect." A later transaction with royalty was not so fortunate, for King CHARLES I. borrowed 500*l.* "out of Sir TH. BODLEY'S cheste." Hope was not abandoned for its recovery until nearly a century and a half later.

The first catalogue appeared in 1605. The arrangement was according to classes; but in the second this was given up in favour of an alphabetical order. Dr. JAMES, in alluding to the growth of the library, remarked that already there seemed to be more need of a library for the books than books for the library. The foundation-stone of the eastern wing was laid in 1610, and the picture gallery was added in 1613-19. An interesting description of the buildings about that time was given by CASAUBON, a Swiss divine and critic, who in 1613 paid his first visit to England. He wrote to a correspondent:—"None of the colleges attracted me so much as the Bodleian library, a work rather for a king than a private man. It is certain that BODLEY, living or dead, must have expended 200,000 livres (about 20,000*l.* at that time if I mistake not) on that building. The ground plot is the figure of the letter T. The part which represents the perpendicular stem was formerly built by some prince, and is very handsome; the rest was added by BODLEY with no less magnificence. In the lower part is a Divinity School, to which, perhaps, nothing in Europe is comparable. It is vaulted with particular skill. The upper storey is the library itself, very well built, and fitted with an immense quantity of books. . . . As long as I remained at Oxford I passed whole days in the library, for books cannot be taken out; but the library is open to all scholars for seven or eight hours every day. You might always see therefore many of these greedily enjoying the banquet prepared for them, which gave me no small pleasure."

In 1610 the Stationers' Company after "many rubs and delays" agreed to give a perfect copy of every book published by their members, on the condition that they

Digitized by Google

should have liberty to borrow the books thus given if needed for reprinting, and to examine, collate and copy the books which were given by others. Two years later an ordinance was passed by the company for enforcing this obligation, and according to which a fine of treble the value of the book was to be imposed on any member who failed to deliver over a perfect copy. But very shortly after, complaints were made as to the failure of the company to fulfil their promise. It was rumoured that Bodley gave the Stationers 50*l.* worth of plate as a return. A hundred years later the first Copyright Act was passed, by which a copy of every work entered at Stationers' Hall had to be deposited in nine libraries—ultimately reduced to five.

Sir Thomas Bodley died in 1613 at the age of sixty-eight, and in accordance with his wish was buried with great solemnity in the upper end of the choir of Merton College chapel. The bulk of his fortune, 7,000*l.* it was said, was bequeathed by him for building the east wing of the library, and the completion of the Schools. But the total proved considerably less "by reason of the fraud of his executor, the loan of a great sum of money to Charles I. in his distress, and by fire of London," when the tenements in Distaff Lane were rebuilt. A mural monument was subsequently erected to his memory in Merton Chapel, for which Nicholas Stone, the sculptor, received 200*l.* It is of black and white marble, and on the top is an effigy of the benefactor in a scholar's gown and surrounded by books.

A hundred years after the opening of the Bodleian considerable alarm was raised as to the stability of the Divinity School, and that portion of the library built over it. About thirty-two years before the roof of the former had shown signs of collapse, and these were rectified by Wren. It is rather curious that John Evelyn, in his diary for July 4, 1654, written at Oxford, says:—"After dinner I visited that miracle of a youth, Mr. Christopher Wren, nephew of the Bishop of Ely. Then Mr. Barlow, Bibliothecarius of the Bodleian Library, my most learned friend. He showed us the rarities . . . furnishing that new part of the library built by Archbishop Laud, from a design of Sir Kenelme Digby and the Earle of Pembrook." In 1692 galleries had been erected on either side of the middle room, and as the beams of the roof of the Divinity School were then observed to give from the wall, they were anchored on both sides. But the tight bracing caused the south wall adjoining Exeter College garden to bulge outwards, so that the bookstalls were found to have started from the walls by 3½ inches at the top and 2½ inches at the bottom. The wall itself was 7½ inches out of the perpendicular, and the four great ribs of the school vault were all cracked. Sir Christopher Wren was called in, and on his advice additional buttresses, of great depth and strength, were erected on the south side; the weight of the bookstalls was removed from the roof by their being trussed up to the walls with iron cramps, and the cracks in the vault were filled with lead or oyster shells, and in some places with the insertion of new stones, and were lastly wedged up with well-seasoned oaken wedges. This work went on through the summers of 1701-2. The letters and papers of Wren on the subject, with drafts and reports of the workmen employed, are preserved in the Bodleian. The plan of placing the bookcases against the walls instead of projecting at right angles into the room was popular on the Continent before its introduction in the Bodleian. Wren ultimately employed this method elsewhere, notably at Trinity College, Cambridge.

A plan for warming the library was first adopted in 1821. It consisted of introducing hot air by two small gratings at one end. The system proved of little benefit except to the few who were in close proximity to the stove. In 1845 pipes were laid down throughout the greater part, but with little improvement. In 1855 on the advice of Mr. Braidwood, the head of the London Fire Brigade, the pipes were enclosed in slate casings so as to effectually hinder contact with inflammable material, and at the same time fireproof doors were inserted at the entrances to the great reading room in order to cut it off from the rest of the building. After a few years' use steam was discarded in favour of hot water.

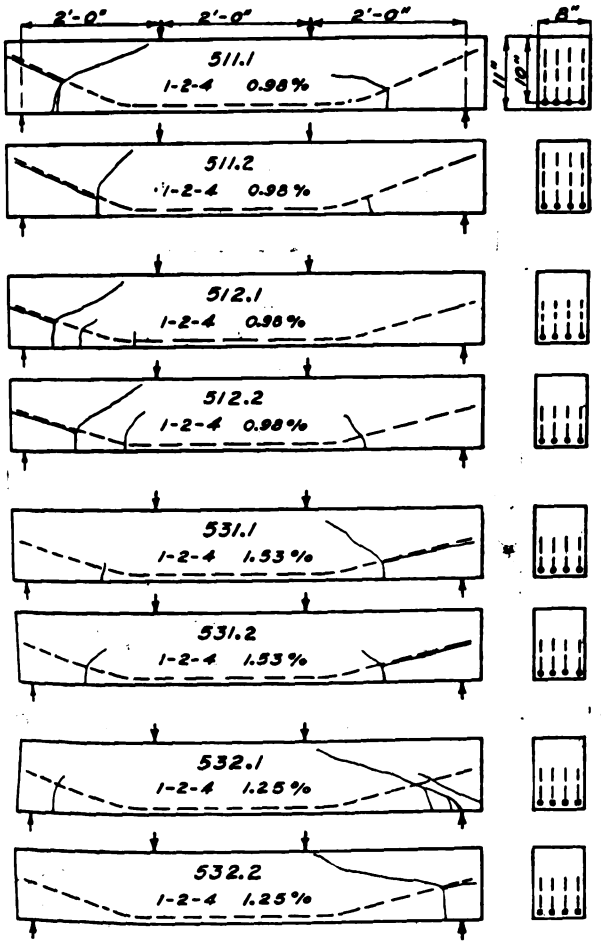
This was chiefly the result of a report by Mr. G. S. Scott, on the enlargement of the library and rendering it fireproof. He suggested an extension of the building throughout the whole of the quadrangle, and that the Divinity School should be assigned as a reading-room, for which use the great amount of light afforded by its large windows appeared peculiarly suited. The subsequent assignment of the Radcliffe Library, however, removed the immediate necessity for further accommodation. In 1902 the Bodleian contained more than 600,000 printed volumes and 31,000 MSS.

Although the library was made the object of other gifts beside books and manuscripts, there does not appear to have been much generosity in presenting objects of architectural interest. In 1620 the first architectural model was presented by Sir Clemens Edmonds. But the greatest acquisition was the bequest of the Arundel marbles. These were allowed to come to serious harm by exposure and wilful damage during the time they were left in the open air within the quadrangle of the Schools. In 1714 they were accommodated in one of the ground floor rooms. More than a century later a subscription was raised for the purpose of adorning the picture gallery with plaster models of some of the finest buildings of Greek and Roman antiquity. As a result the following series by Fouquet, of Paris, was placed in the gallery at a total cost of 400*l.*:—The Arch of Constantine, the Parthenon, the Temple of the Sibyl at Tivoli, the Maison Carrée at Nîmes, the Erechtheum, the Lantern of Demosthenes at Athens, the Theatre of Herculaneum, and the Temple of Fortuna Virilis at Rome. The Sutherland Collection, presented in 1837, includes 309 views of London and 166 of Westminster. Among the former is the well-known series of drawings by Antonio van den Vyngaerde, executed between 1558-63.

Holt is believed to have been the architect of the Jacobean buildings which, with the Bodleian, formed a great quadrangle. The gate tower is a conspicuous feature. In the uppermost storey a gilt statue of James I. was placed. It is said that the sceptre fell from that monarch's hand at the shock of William IV.'s accession.

Such is a brief outline of the history of this famous library. Robert Burton in the "Anatomy of Melancholy" wrote:—"How much are all we bound that are scholars to those munificent Ptolemies, bountiful Mæcenases, historical patrons, divine spirits that have provided for us so many well furnished libraries? How shall I remember Sir Thomas Bodley among the rest?"

TESTS OF REINFORCED CONCRETE BEAMS.



THE resistance to failure by shear and diagonal tension, and the effectiveness of metallic web reinforcement, are discussed in Bulletin No. 29, Tests of Reinforced Concrete Beams: Resistance to Web Stresses, by Arthur N. Talbot, just issued by the Engineering Experiment Station of the University of Illinois. This bulletin of 85 pages gives the results of tests made in the Laboratory of Applied Mechanics of the University. The strength and quality of the concrete itself are shown to have a marked effect on web resistance, and the importance of securing a high grade of concrete in beams subject to large web stresses, even if metallic web reinforcement is used, is brought out strongly. Data are given on which to base the age necessary to enable concrete to take shearing stresses. It is established that the less the ratio of length of span to depth of beam the greater the shearing resistance developed per unit of cross section, and also that the greater the amount of longitudinal reinforcement the greater the shearing resistance. Both effects depend upon added stiffness, a relation which has not been formulated before. Several types of web reinforcement were investigated, bent-up longitudinal bars of different forms, unit frames, vertical stirrups of different sizes and proportions, smooth and deformed bars, &c. The notes and discussions given add to the value of the matter for those who wish to study the details of the tests. The analytical treatment of web stresses, the discussion of the experiments, and the remarks on proportioning stirrups may all

Digitized by Google

be helpful to engineers. Although a considerable fund of information bearing on the part taken by the resistance of longitudinal reinforcement, and the compressive resistance of concrete has accumulated, the data of web stresses are less definite and less complete. This monograph is therefore timely, and it ought to take rank as an important contribution to the literature of reinforced concrete.

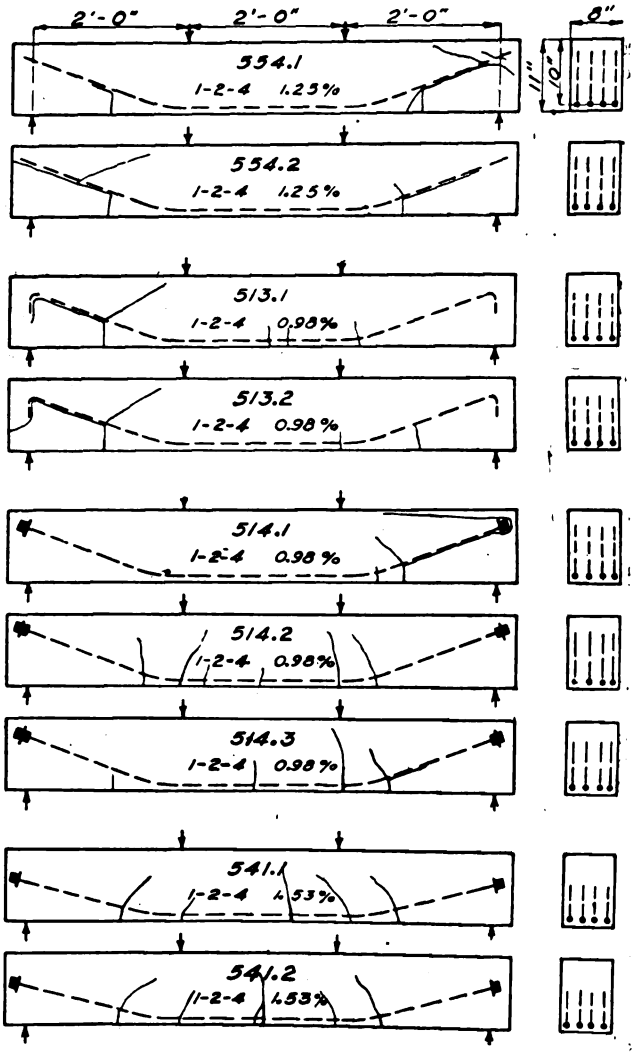
Copies may be obtained gratis upon application to the Director, Mr. L. P. Breckenridge, Engineering Experiment Station, Urbana, Illinois.

The following are brief notes of the tests of beams with the reinforcing bars bent up. The location of the cracks is shown in diagrams. The heavy lines indicate cracks along which failure took place:—

No. 511.1. At 13,000 lb. the first noticeable crack appeared at 2 feet to right of centre and extended from the bottom vertically 3 inches to the level of the reinforcement and then diagonally toward the load point 5 inches. At 14,000 lb. a vertical crack appeared 2 feet 5 inches to left of centre and extended to the reinforcing bars. From this point it finally ran diagonally almost to the load point. The beam failed at 18,000 lb., the crack following the reinforcing bars to the end of the beam. The load then dropped quickly to 6,000 lb., where it remained constant for some time.

No. 511.2. At 13,000 lb. a crack appeared 1 foot 10 inches to left of centre and extended to the reinforcing bars. At 15,000 lb. this crack had extended diagonally almost to the top of the beam, 4 inches to the left of the load point. The load of 15,000 lb. was held for 15 minutes, due to a break in the machine. The beam failed at 20,000 lb., the load then dropped slowly to 4,000 lb., and the crack on the left extended along the reinforcement almost to the end of the beam. An examination of the beam made afterward showed that the bars had slipped $\frac{1}{4}$ inch in the left end.

No. 512.1. At 15,000 lb. two cracks were noted, one 2 feet 5 inches to the right and the other 2 feet 1 inch to the left of centre, extending upward to the reinforcing bars. At 18,000 lb. a crack appeared 2 feet 6 inches to the left of centre and extended to the reinforcing bars, branching off diagonally to the right toward the load point and to the left along the reinforcing bars. The maximum load was 19,000 lb. and the load gradually dropped to 2,000 lb. An examination of the beam showed that the rods at the left end had slipped slightly. The crack had followed the reinforcing bars to the end.



No. 512.2. At 14,000 lb. a crack appeared 1 foot 5 inches to left of centre and extended toward the load point. At 16,000 lb. a crack was observed 2 feet 2 inches to left of centre, which extended vertically to the reinforcing bars and from here started toward the load point. The beam failed quite suddenly at a load of 17,350 lb., and the crack followed the reinforcing bars to the end of the beam. An examination of the beam showed that the bars had slipped $\frac{1}{8}$ inch.

No. 531.1. This beam failed in a manner similar to No. 512.1 and at a load but 500 lb. greater. The crack at 1 foot 10 inches to right of centre appeared at 14,000 lb. and the beam failed at 19,500 lb., the crack following the reinforcing bars to the end of the beam.

No. 531.2. At 12,000 lb. a crack appeared 2 feet to left of centre and extended vertically to the reinforcing bars. At 18,000 lb. this crack was 5 inches above the bottom and was extending toward the left load point. At 14,000 lb. a similar crack appeared 2 feet to right of centre and extended in the same way. At 22,000 lb. a slight hair crack was noted following the line of the reinforcement. The beam failed by the opening of the crack at 24,000 lb.

No. 532.1. At 18,000 lb. a diagonal crack appeared at 2 feet 5 inches to right of centre and the beam finally failed along this crack. The maximum load was 20,000 lb.

No. 532.2. At the maximum load of 18,000 lb. a diagonal crack extended from the right end toward the load point. The bars slipped after the diagonal tension failure occurred.

No. 554.1. At 13,600 lb. a vertical crack appeared 1 foot 10 inches to left of centre and one 2 feet to the right of centre, which extended 4 inches high to another crack. At 17,900 lb. the beam failed as shown in the sketch in Fig. 14.

No. 554.2. At 10,800 lb. a vertical crack appeared 2 feet to the left of centre, extending up to the reinforcement, thence along the reinforcement to the end of the beam. A similar crack appeared 1 foot 9 inches to the right of centre. At a maximum load of 17,500 lb. the beam failed along the crack to the left of centre.

No. 513.1. At 9,000 lb. a crack appeared 2 feet to left of centre and extended vertically to the reinforcing bars. The

Digitized by Google

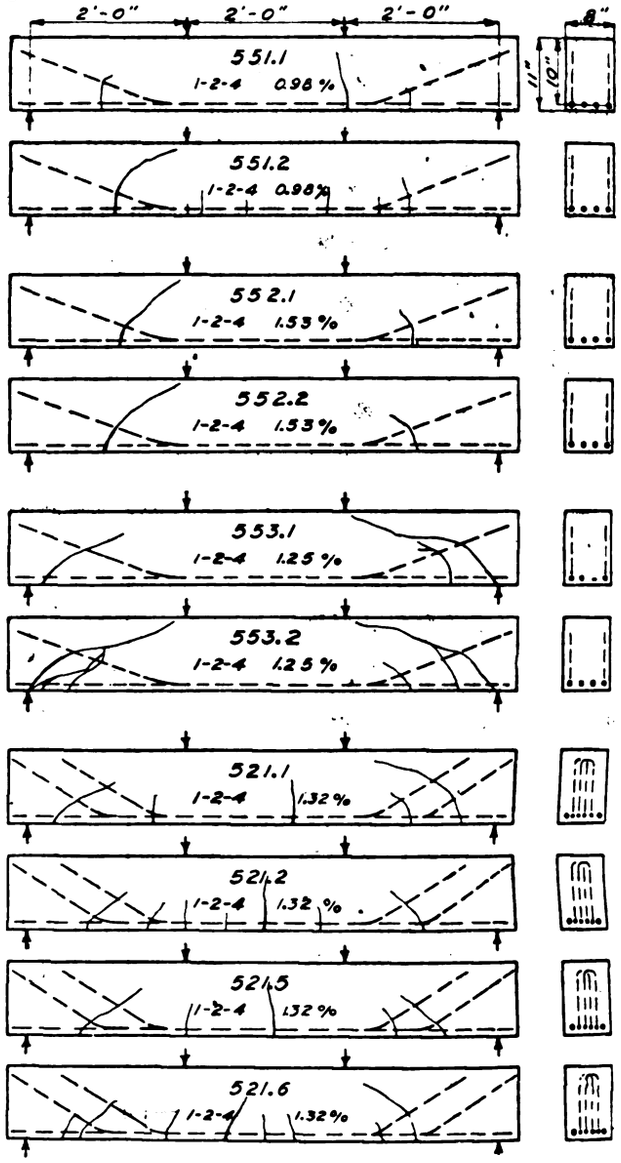
beam failed suddenly at 16,700 lb. The crack followed the reinforcement to its end.

No. 512.2. At 10,000 lb. a crack appeared 2 feet to left of centre, extending vertically to the reinforcing bars. As the load increased this crack extended diagonally toward the load point. The beam failed at 16,400 lb.; this crack following the reinforcing bars to the end.

No. 514.1. At 10,000 lb. a crack appeared at 1 foot 10 inches to right of centre and extended to the reinforcement. The beam failed suddenly at 21,100 lb. by this crack running along the reinforcement to the nuts. At failure a crack appeared at the nut, running back toward the load point. The diagonal crack shown closed up. This is a peculiar failure and differs from others of its set. As noted elsewhere the washers were not locked to the end nuts in this beam.

No. 514.2. This beam is noteworthy because it failed through tension in the steel, although a crack was visible along the reinforcing bars. At 14,000 lb. a crack appeared to the right of the right load point and finally extended some distance toward the load point. At 19,000 lb. slight cracks were seen following the reinforcement from this crack. At 16,000 lb. a vertical crack 3 inches long appeared at the centre and also a crack below the left load point which extended upward 4 inches. At the maximum load of 22,200 lb. this crack was 8 inches high, and opening considerably, showing failure by tension in the steel. At 18,000 lb. a vertical crack 6 inches long was noted 1 foot 6 inches to left of centre and at the maximum load it was 8 inches long. The deflection of the beam at the maximum load was 0.2 inches, and the load remained within 1,000 lb. of the maximum until the deflection was 0.43 inches. Crushing of the concrete at the top of the beam occurred under the increased deflection.

No. 514.3. At 12,000 lb. a crack appeared 1 foot 8 inches to right of centre and extended vertically 4 inches. At 18,000 lb. a crack had branched off from the first crack and followed the reinforcement for a short distance. At 22,000 lb. a crack appeared under the right load. At the maximum load of 23,500 lb. this crack was 8 inches high, and as the deflection of the beam was increased the crack opened up almost to the top of the beam, and finally the concrete began to crush at the top. The beam failed by tension in the steel. The effect of the anchorage is shown in that the inclined crack did not extend to the end of the bar.



No. 541.1. At 16,000 lb. the first crack appeared at 1 foot 10 inches to left of centre and was 2½ inches long. At 18,000 lb. it had extended toward the load point until it was 5 inches from the bottom of the beam and at 28,000 lb. it was 7 inches. A similar crack appeared at 1 foot 10 inches to right of centre at 18,000 lb., and at 26,000 lb. this crack was visible 7 inches above the bottom of the beam. At 18,000 lb. cracks were noted under the two load points. At 22,000 lb. a crack 5 inches to right of centre was 2 inches high. At the maximum load of 29,600 lb. this crack was 6 inches long. This load was held almost constant for some time and the beam failed by tension in the steel, followed by crushing of the concrete at the top of the beam.

No. 541.2. This beam failed in a manner similar to No. 541.1. At 12,000 lb. the first crack appeared 1 foot 7 inches to right of centre and extended 4 inches toward the load point. At 14,000 lb. a similar crack appeared 1 foot 10 inches to left of centre. At 16,000 lb. this crack was 8 inches above the bottom of the beam. At 16,000 lb. a small vertical crack was observed near the centre. The maximum load was 28,450 lb. The beam failed by tension in the steel.

No. 551.1. At 14,000 lb. a crack appeared 1 foot 10 inches to right of centre, extending vertically 3 inches. At 16,000 lb. a similar crack appeared 2 feet 1 inch to left of centre. At 22,000 lb. a slight vertical crack was noted under the right load point. This gradually extended upward until the maximum load of 24,700 lb. was reached. The beam failed by tension in the steel and an examination showed that the rods had scaled. The cracks in the other one-third did not develop to any extent.

No. 551.2. At 14,000 lb. two cracks appeared; one 2 inches long at the right one-third point and one 4 inches long near the left one-third point. At 16,000 lb. a vertical crack 6 inches long was noted 1 foot 11 inches to left of centre. At 18,000 lb. three more vertical cracks were noted in the middle third. The beam failed at a load of 22,000 lb. by the crack in the left third of the beam extending to the load point, and at the same time following the line of horizontal reinforcement. This diagonal tension failure was at a load which nearly developed the elastic limit of the steel.

No. 552.1. At 22,000 lb. a crack appeared 10 inches to left of left load point 5 inches high and at 23,000 lb. one 14 inches to right of right load point 4 inches high. Failure at 25,000 lb. by the extension of the first crack to the load point.

No. 552.2. At 24,000 lb. a crack appeared 10 inches to right of right load point 5 inches high, and at 25,000 lb. one 17 inches to right of right load point 5 inches high. At 28,000 lb. these cracks were opening and lengthening. At 30,000 lb. the cracks were extended well toward the load point. Final failure came at the left end, the crack reaching from support to load point.

No. 553.1. At 24,000 lb. a diagonal crack appeared 2 feet 4 inches to right of centre and at 24,700 lb. one at 2 feet 10 inches to left of centre. These cracks gradually lengthened, and at 28,800 lb. the beam failed by diagonal tension. It will be noted that the failure crack extended to the support.

No. 553.2. At 24,000 lb. a diagonal crack appeared 1 foot 10 inches to right of centre, at 25,000 lb. another at 2 feet 5 inches to right of centre, and at 26,000 lb. one at 2 feet 6 inches to left of centre. These cracks gradually opened and lengthened, and at 31,000 lb. the maximum load was reached. The crack at the right end extended almost to the load point, and the final failure came at the crack at the left end, which reached from support to load point.

No. 521.1. This is the Cummings' unit frame reinforcement. It should be noted that the cracks outside the load points were small and did not extend far, and that failure was by tension in the steel at a high vertical shearing stress. At 20,000 lb. the first crack appeared at 4 inches to right of centre and extended upward 4 inches. At 22,000 lb. a crack appeared 2 feet 6 inches to right of centre, extending upward 6 inches. Another crack 4 inches long was noted 1 foot 5 inches to the left of centre, inclined toward the load point. At 28,000 lb. slight vertical cracks were noted 1 foot 10 inches to right of centre and 2 feet 8 inches to left of centre. The beam failed by tension in the steel at the crack near the centre, the maximum load being 31,100 lb. The load ran near the maximum for some time, as the deflection was increased, and finally the concrete crushed slowly at the top.

Digitized by Google

No. 521.2. Another Cummings' reinforcement. The first noticeable crack was at the centre of the beam at 16,000 lb., extending upward 3 inches. At 18,000 lb. a slight crack appeared at the left one-third point. At 20,000 lb. two cracks appeared both inclined toward the load points, one 2 feet 3 inches to left of centre and the other 2 feet to right of centre. At 22,000 lb. a vertical crack appeared at 8 inches to right of centre and at 24,000 lb. at 6 inches to left. At 26,000 lb. a crack 6 inches long appeared 1 foot 6 inches to left of centre and inclined toward the load point. At the maximum load of 35,000 lb. the crack at the centre had gradually extended, opening up, and the beam failed by tension in the steel. The load remained near the maximum until further deflection and crushing of the concrete at the top of the beam finally occurred. The beam held 34,000 lb. until a deflection of nearly 0.5 inch had been reached. The outer cracks had not developed particularly, and there was no appearance of cracks in the direction of the reinforcement.

No. 521.5. Another Cummings' reinforcement. At 20,000 lb. a crack appeared 2 feet 3 inches to right of centre, inclined slightly toward the left. At 24,000 lb. slight vertical cracks were noted at the left one-third point. At 26,000 lb. a crack appeared 2 feet 4 inches to left of centre and inclined toward the load point. At this load a vertical crack 2 inches long was observed 1½ inches to right of centre. At 32,500 lb. this crack had opened almost to the top of the beam, and the beam failed by tension in the steel. The load carried dropped, and crushing of the concrete finally occurred.

No. 521.6. Another Cummings' reinforcement. At 16,000 lb. an inclined crack 6 inches long was visible 2 feet 4 inches to left of centre. At 18,000 lb. an inclined crack 1 foot 11 inches to right of centre appeared, which at 26,000 lb. had extended 8 inches from the bottom of the beam. It finally reached almost to the load point. At 18,000 lb. a vertical crack 2 inches long appeared 6 inches to left of centre. At 20,000 lb. a vertical crack 2 inches long was noted at the centre of the beam. The beam carried a maximum load of 26,200 lb. The deflection diagram is somewhat different from the other beams. The method of failure was evidently by tension in the steel aided by a yielding of the concrete which decreased the moment arm. The stress in the steel is therefore greater than the calculations make it. There was evidence that the concrete in this beam was not so good as in the other beams.

(To be continued.)

ART EXHIBITIONS.

THE many admirers of Mr. George Clausen's art have now a splendid opportunity for penetrating below the surface of his work and gaining an insight into his methods. For in the Hogarth Room of the Leicester Galleries there is an exhibition of sixty paintings and drawings by Mr. G. Clausen, R.A., R.W.S., which have never before been shown. It is not improbable that the first sensation of many of the enthusiasts will be something akin to disappointment, for there is little that can add to the artist's reputation. "The Visit" is certainly an altogether charming and very clever picture; but the painting of two figures in a window, with the consequent light effects on the interior of the room, has been ably done by others also. The ruggedness of the veteran's head in "An Old Villager" is most captivating, and the same attraction belongs to the head of "Kitty." Another conspicuous work is "The Rickyard: a Sunny Day," which is in his best manner. Of his slighter works mention may be made of "The Village at Night," "Winter Morning" and "Evening after Rain." There are several flower pieces and studies of still life; these prompt a doubt whether Mr. Clausen might not devote his time and talent to more personal work.

Messrs. Dowdeswell have organised in their New Bond Street Galleries a loan collection of pictures by Jan Steen, in aid of the National Hospital for the Paralysed and Epileptic. The great Dutch artist is represented by thirty-nine of his works, and these, with one exception, come from English collections. It has been said that "of all the Dutch painters of familiar life Jan Steen is acknowledged to be the greatest genius. The humour and whim in his compositions disclose to us a mind quite distinct from the rest, and the love of childhood displayed in his works shows that with all his eccentricities there is something good in his nature." A striking instance is in No. 21, *Grace Before Meat*, which is touching in its devotional simplicity; but Jan Steen was apparently ashamed of so much innocence, so he introduced a scamp of a boy who, despite the frowns of his father, is mockingly laughing while his little sister is being taught to say Grace. It mght well be the product of the merry rogue shown in No. 35, which is a whole-length portrait of the artist singing while he plays a mandoline. The majority of the pictures, however, seem to revel in the sordid details of tavern and peasant life. This same spirit inspired the *Marriage at Cana*, in which the performance of the miracle becomes of quite secondary importance. His axiom must certainly have been "Eat, drink, and be merry, for to-morrow we die"; and it was in painting wedding feasts, village fêtes, and acts of dissipation that Jan Steen seems to have felt most at home. The excellence of his colouring was warmly praised by Reynolds, and it is claimed that he painted dirt without it looking dirty. It is certainly true that the colouring of his pictures is fresh and bright. But we think the visitor to the galleries will wish the artist had felt an attraction for cleaner subjects.

NOTES ON BOOKS.

"The Building Foreman's Pocket Book and Ready Reference." By H. G. Richey. (New York: John Wiley & Sons. London: Chapman & Hall, Ltd. 21s. net.)

WRITTEN from an American standpoint, this book is of necessity of less value on this side of the Atlantic than in the States; for example, in treating of Portland cement the standard sieve and standard sand used for testing in America convey no meaning to an English reader. The names of things and methods used on the other side do not always correspond to those with which we are familiar here. Notwithstanding these inherent disadvantages, this pocket-book is a very useful collection of information on all sorts of subjects for those who have to superintend building operations. From the orders and ornaments of Classic architecture to first aid to the injured there are few things that a foreman can learn from books that are not touched by this, and when work is done there are a few amusing puzzles "for the noon hour."

Perhaps to an English reader the most useful portions of the book are those dealing with the operative part of concrete construction, the methods of preparing moulds and centering, and various dodges and tips which the more extensive use of concrete in the States has naturally added to the stock of knowledge of the American workman. The laying out of work is well explained with practical methods of full size geometrical drawing, including curves of various kinds, conic sections and others, an essential part of a foreman's mental equipment. Similarly useful is what the author calls "Short cuts and useful problems," under which heading he deals with the use of ropes and their knots and a variety of miscellaneous information both curious and useful. The book, in short, is what it professes to be—a handy book of reference for the pocket of the building foreman. For the architect who has sometimes to tell a foreman what to do it provides just the sort of information that would impress the workman with a respect for the architect's practical knowledge.

OUR CONTEMPORARIES FROM OVER-SEAS.

THE *American Architect* devotes its illustrations to moderate-sized country houses, in which shingles, tiles, rubble, stone and plaster are the materials employed, and reproduces the R.I.B.A. recently issued list of books for students.

La Construction Moderne has an interesting review, with illustrations, of M. de Dartein's volume on "Ponts Français du XVIII. Siècle (Bourgogne)," the purport of which is to show the artistic character of the stone bridges of Burgundy during the eighteenth century. Illustrations are given of the monument to J. Lalande at Bourg and to Ch. Floquet at Paris, M. T. Ferret being the architect and M. Muscat the sculptor of the former, and M. Viet and M. Descombs respectively the architect and sculptor of the latter.

The *Engineering Record* (New York) gives an account of the use of built-up concrete slab piles as employed for the repair of old timber piers and piles at Southampton, Cowes, Ryde, and Portsmouth. The description of the central heating and lighting plant at the United States Military Academy is continued.

[The Editor will not be responsible for the opinions expressed by Correspondents.]

The Conference on Taxation of Land Values.

Sir,—The land tax proposals in the Budget will, if adopted, so seriously affect all classes of property owners that it is incumbent upon all to make their opinions known without delay.

Anticipating the proposals of the Budget, the Council and committee of the British Constitution Association passed the following resolution on April 23 last:—

"That this meeting is strongly opposed to the suggested taxation of land values for the following reasons (among others):—(*a*) It would single out for taxation a class of property owners who already bear more than their fair share of imperial and local burdens; (*b*) it would impair the security of all mortgagees of land and owners of ground rents, among whom are the great friendly societies and other provident institutions; (*c*) it would unnecessarily disturb and dislocate land business throughout the country, and impose increased expense and possible loss on the large class of persons who have borrowed on the security of their landed property."

The resolution unanimously passed by the largely attended Conference of Representatives of Organisations connected with Land on Friday last was in the following terms:—

"That this Conference hereby resolves in regard to the land taxation proposals of the Budget:—(1) That they are unjust, because they would penalise certain sections of the community for the supposed benefit of others. (2) That they are impolitic, because they are calculated to provoke resentment on the part of those thus imposed upon, in the same way as did the levy of ship money in the reign of Charles I. (3) That they are economically unsound and calculated to impair the security of all property, and, through property, of every trade and industry in the country. (4) That a committee be appointed to prepare and present to His Majesty's Government a memorial urging the Government to withdraw the land taxation proposals. (5) That the committee consist of one representative from the Surveyors' Institution, the Society of Architects, the Estate Agents' Institute, the Central Land Association, the Central Chamber of Agriculture, the Metropolitan Public Gardens Association, the Auctioneers' Institute, the Incorporated Association for the Protection of Property Owners, and the executive officers of the British Constitution Association, with power to add to their number. (6) That the Conference at its rising stand adjourned to a time to be fixed by the committee to consider the reply of the Government."

We shall be glad if you will allow us, on behalf of the British Constitution Association, to inform your readers that all professional, trade or other organisations are invited to appoint four representatives to attend the adjourned meeting of the Conference, which will be held to consider the reply of the Government to the memorial and at which Lord Balfour of Burleigh will preside. Organisations agreeing with the resolution passed by the Conference are requested to so inform the hon. secretary of the Conference, in order that such agreement may be embodied in the memorial.—We are, &c.,

Avebury.
William Chance.

Wilbraham V. Cooper.
Mark H. Judge, Hon. Sec. to the Conference.

23 Charing Cross, London, S.W.: May 21, 1909.

Bishopstone Church, Wilts.

Sir,—The following notes on this church, of which you recently published a sketch, may interest your readers. They are based on information for which I am indebted to the courtesy of the Rector, the Rev. Archdeacon Lear.

The church, which is one of the most interesting village churches in the South of England, is dedicated to St. John Baptist, and is cruciform with a square tower at the crossing. The south transept shown in the sketch is vaulted, as is the choir, and the tracery is of unusual type, occurring as it does below the arch springing, and being quite Flamboyant in type. The small building against the gable wall is not as might be imagined a porch, having no entry into the transept, and its use has been much discussed by archæologists without finality. The Rector thinks, after much search, that it was erected simply to get decorative effect, and if this be so it seems to me to deserve to be called unique. It is beautifully groined, and is covered with a stone roof. The building was measured and described by Owen Carter, and the result published in Weale's "Quarterly Papers on Architecture," vol. 4.

All the work shown in the sketch is of the date of Edward III., and is of great beauty of workmanship. It was in the gift of the see of Winchester, and William of Wykeham presented the living in 1379 to John of Wykeham.—Yours faithfully,

E. Godfrey Page.

2 Old Serjeants' Inn, Chancery Lane.

Norfolk Reeds as Roofing.

Sir,—I have applied to the Welwyn Rural Council to ask if I can cover a house with Norfolk reeds, such as used in Norfolk, and they answer by saying that at the present moment they cannot see their way clear to grant my request.

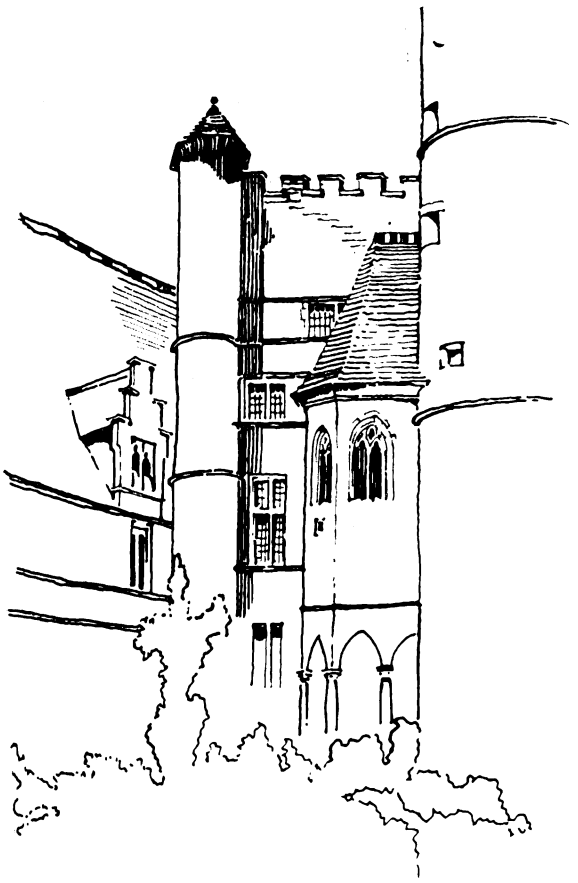
In the neighbouring counties, Bedfordshire has no objection to the reeds being used, or Cambridgeshire; they are also allowed at the Garden City, Letchworth. I am afraid the Welwyn Rural Council are not of an artistic mind. They have some cottages in their own district covered with straw thatch.—Yours faithfully,

F. Newton.

94 Tilehouse Street, Hitchin.

[The Welwyn Rural Council appear to be unaware that Norfolk reeds are less inflammable and more sanitary than straw thatch, besides being preferable from an artistic point of view.—Ed.]

GENERAL.



Mr. R. G. Thomas, architect, died last week at his residence, Victoria Hotel, Menai Bridge. Mr. Thomas, who was sixty-two years of age, nearly a fortnight previous went up a ladder to the roof of the hotel to examine some repairs, and, the ladder being too short, he overreached himself and fell a distance of 30 feet, sustaining injuries from the effects of which he died.

The Newcastle Board of Guardians have received a letter from the Local Government Board with reference to the plans of the proposed extensions to the hospital. A few alterations were suggested by the letter. The estimated cost of the alterations was 18,000*l*. It was agreed that the plans be forwarded to the Local Government Board for approval.

The Royal Geographical Society at their anniversary meeting on Monday passed the following resolution:—"That in the opinion of this meeting it is desirable to build or purchase a house or site elsewhere, or to rebuild, enlarge, or remodel the existing house; that, if the funds admit, a hall, to be called the Explorers' Hall, designed both to commemorate explorers and to serve as a meeting place for the Society, should form a prominent feature in the new or rebuilt house; and that, even if no other step be taken, a building fund should be created for accumulating capital for these purposes."

The Secretary to the Treasury, as representing the Commissioners of Woods and Forests, was asked last week whether his attention had been called to the fact that while royalties on slate quarries on Crown property in North Wales are between 2*s.* 10*d.* and 3*s.* 5*d.* per ton, the average royalty on quarries on private property is between 2*s.* and 2*s.* 6*d.*, and whether he would have an inquiry made into the scale of royalties on Crown property. Mr. Hobhouse, in a printed reply, said the Crown royalties on slates are in nearly all cases charged in the form of a percentage on the sums realised by the sale of the slates. Consequently they rise and fall with the fluctuations of the market, and when prices are low leases get the benefit of an automatic reduction. The whole question of royalties on the principal Crown quarries in Carnarvonshire was very carefully and thoroughly gone into by the Commissioners of Woods five years ago. The case of each quarry was considered and dealt with on its own merits. Considerable concessions were made, and the lessees united in expressing their appreciation of the fair spirit in which their applications had been met.

RUE DU SÉMINAIRE, GHENT.
From a Sketch by BANISTER FLETCHER.

THE WEEK.

THE important memorandum by the Council of the Surveyors' Institution on the Budget proposals for the taxation of land, and the deputation from the Institution, received by Mr. C. E. H. HOBHOUSE, Financial Secretary, in the absence of the Chancellor of the Exchequer, ought to enlighten the minds of the Government, and particularly that of Mr. LLOYD GEORGE, as to the effect upon landed property of the proposed taxes. No society in the kingdom is better qualified than the Surveyors' Institution to estimate the effect of the Budget proposals upon landed property, whether developed or undeveloped, upon ground rents and leaseholds, upon mining royalties, actual and prospective. We give elsewhere the text of the memorandum which formed the subject of the representations made by Mr. A. R. STENNING, F.R.I.B.A. (President of the Surveyors' Institution), Mr. HOWARD MARTIN (Past President), Mr. J. K. SABIN, Mr. HERBERT SMITH, and the Secretary (Mr. ALEXANDER GODDARD), who formed the deputation.

THE Dean and Chapter of Chichester Cathedral are appealing for funds for the further repair of their church, and accompany with their appeal a report on the progress that has been made during the last four years and on the work that remains to be done. The repointing of the exterior, which was commenced in 1902, has been in progress ever since, and has been completed from the south transept eastward and round to the north-west tower, thus leaving the west front, the south-west tower—which needs more repair than merely repointing—and the south side of the nave and chapter house. Since the Executive Committee last reported, four years ago, the detached campanile or bell-tower has been thoroughly repaired at a cost of 2,300*l*.

TROUBLE has occurred in the vaulting, the penultimate bay of the nave at the west end having developed serious signs from an old crack. This local fault has been dealt with, the loose, disintegrated, and cracked chalk ashlar has been pinned up, and the rib stones properly secured. The outbreak of this trouble has caused the architect to advise an immediate careful examination of the whole of the vaulting of the nave and choir, so that any defects may be remedied before they become serious. This is the proper course for custodians of our ancient cathedrals to adopt, careful and frequent examination and prompt repair of small defects before they become great. Compared with this, the completion of the pointing and the repair of the west front, though urgent, are less immediately so. The renewal of the lead roof is another matter that should be attended to at an early date, and for which funds may well be specially contributed by lovers of Chichester Cathedral, although the work is, in the opinion of the architect, not pressingly urgent at the moment. It should not, however, in our opinion, be too long delayed, as a leaking roof over chalk vaulting is clearly a condition that invites serious disaster. The requirements of the Dean and Chapter of Chichester are so moderate, compared with those of some other cathedrals, that we hope all cause for anxiety will speedily be removed by an ample and prompt response to their appeal.

THE Council of the Cardiff, South Wales, and Monmouthshire Architects' Society has done well to protest against the resolution of the City Council of Cardiff to entrust the design of a new school to the city engineer. The small amount apparently—and only apparently—saved, in architect's fees by the carrying out of such specialised work as school planning in an official department is quite unworthy of consideration in a matter of so much importance to the health of the children and the efficiency of their education as the provision of the absolutely best and most up-to-date school buildings. It is ludicrous to suppose that an engineer's assistants, working overtime, and therefore presumably overtaxed, can produce plans for schools that can in any way compare favourably with those of architects who have given years of study and gained large experience in this by no means simple branch of architectural practice. It may appear to an ordinary councillor that it is an easy matter to design a school, and so it is, of sorts, but it is far from easy to design the best possible school for any particular case.

THE case of BROWN *v.* Llandovery Terra Cotta, &c., Company, Ltd., is important for those who may be called upon to act as arbitrators. In a dispute between JOHNSON, Ltd., and the defendants, Mr. BROWN was appointed arbitrator on behalf of or by JOHNSON, Ltd., and Mr. NORMAN on behalf of or by the defendants. These two arbitrators, having failed to agree, referred the dispute to Mr. SMART, as umpire, and he, in his award, ordered the defendants, the successful party in the arbitration, to pay the charges of Mr. BROWN, but left Mr. BROWN to recover those charges from the defendants. The arbitration was subject to the Arbitration Act, 1889. Mr. Justice SUTTON, who tried the action, in his judgment said:—"Whether or not the plaintiff is entitled to recover depends upon the question whether there is an implied promise by the parties to the submission jointly to pay the arbitrators and umpire for their services. I think this question must be answered in the affirmative on the authority of 'CRAMPTON and HOLT *v.* RIDLEY & Co.'" The learned judge therefore gave judgment for Mr. BROWN, the plaintiff.

THE value of a "holy well" as an asset of a mediæval church is strikingly illustrated by the instance of the discovery in 1872 of what are generally believed to have been the remains of the church of S. Cesario in Palatio, a small fifth-century building, which the famous Italian archæologist, Commendatore BONI, is now exploring. A well, of evidently Republican date, has connected to it a staircase of the same date as the church. Holy wells of high reputation existed in Greek lands, in Rome, and in other parts of Europe, even as far west as Ireland, in pagan times, which were afterwards adopted by the astute churchmen of the middle ages as suitable adjuncts to the site of a Christian church and as a good attraction for pilgrims.

ARCHITECTURE AT THE ROYAL ACADEMY.—III.

COMING now to the section of the Architectural Room devoted to drawings of buildings for scholastic or other educational purposes, we find that there is not comparatively so large a proportion of noticeable designs as in other sections. The requirements of modern schools necessitate a considerable number of rooms of nearly, if not quite, the same size and more or less of the same pattern; hence it is difficult without forcing for an architect to design a school building in which repetition of treatment is not conspicuous.

The first drawing numbered in the catalogue is a "Hostel for Women Students at the Birmingham University," by Messrs. H. T. BUCKLAND & E. H. FARMER, which is a large house on an H plan, in which a domestic character is maintained without too much idea of an institution. "Wantage Hall, University College, Reading: Interior, Great Hall," by Mr. C. STEWARD SMITH, as shown in the perspective, appears principally to consist of a hammer-beam roof too large for the height of the walls on which it is supported. Mr. ARNOLD MITCHELL'S "Agricultural Buildings for the University of Cambridge," though lacking any feeling of the local spirit of our older Universities, is dignified and restrained, and, as shown in the coloured pencil elevation, is of stone and purple brick. We hope the colourist has taken artistic license in his delineation of the colour of the bricks. Mr. W. D. CARÖE'S design for "The Library, University of South Wales and Monmouthshire," like most of that architect's work, is overdone with detail, though far less so than has been the case in the past. In fact, the buildings here shown are quite dignified by comparison with some of Mr. CARÖE'S previous efforts, and would be still more so if the meaningless pilasters carrying nothing but inverted trusses were omitted.

The buildings designed for the "Village in the Elan Valley, Wales," by Messrs. H. T. BUCKLAND & E. H. FARMER, are very picturesque in grouping and unaffected treatment of stone and slate. Mr. AYLWIN O. CAVE'S "Secondary School for Boys, Maidenhead," is an unsuccessful competition design, of which it is difficult to appraise the merits without a plan. As far as the perspective shows, the chief feature of this is the placing of class-room blocks at right angles to each other, with other buildings—possibly the central hall—between, a disposition that makes for picturesqueness even if not leading to good planning.

Mr. HENRY T. HARE'S "University College of North Wales, Bangor," shows in an excellent water-colour drawing a stone building of Tudor domestic or college type, picturesque and yet dignified. Although not scholastic, "A Georgian Dining Hall," by Mr. H. DAVIS RICHTER, is hung in the educational section. It is rather too gorgeous for anyone but a South African or Chicago millionaire, who might be expected to appreciate a dining-room called "Georgian" and costing a lot of money. "The Coopers' Company's Schools, Bow," by Messrs. T. P. FIGGIS & A. E. MUNBY, is a good design, gaining much in its impressiveness by the circular colonnade in front of the quad, around which the school buildings are disposed.

Mr. PAUL WATERHOUSE'S beautiful drawing of "A Design submitted for the Eton Memorial" shows the detail of a part only of a beautiful and scholarly design. "A Design for Ruskin College, Oxford," by Mr. C. STEWARD SMITH, is a bird's-eye view of an interesting and well-grouped block of buildings. Messrs. SPALDING & SPALDING and E. G. THEAKSTON have contrived in their "High School for Girls, Stockport," to combine picturesqueness with formality in a manner that seems to us the most suitable line of effort for the designer of a school. "Newlands, Congleton," by Mr. REGINALD T. LONGTON, is out of its place in this section, being a simple and refined picturesque house, but it just happened to fill a gap in the hanging space, though being a small drawing it must, of course, be hung on the skirting, as near the floor as possible.

Professor F. M. SIMPSON'S "Physiology Institute, University College, University of London," is a scholarly and refined detail drawing, shown in a tinted elevation. Mr. BURKE DOWNING'S "Bromley Boys' Secondary School" is a beautiful drawing of a well-grouped symmetrical design of the formal picturesque type that we have already commended as the most appropriate treatment for a school. Mr. EUSTACE C. FRERE'S "Additions to All Saints' School, Leyton," is an example of the way in which a skilful draughtsman can make a pretty water-colour drawing of a quite uninteresting building.

We now come to the section of the exhibition in which domestic work is collected, and first notice Mr. L. ROME GUTHRIE'S "Gardens at Chetwood-Vetchery," a well-drawn bird's-eye view of a good scheme of formal garden design. Mr. EDWIN L. LUTYENS, in his "New West Wing, Temple Dingley, Herts," and his "Garden View of a House at Ilkley," gives us examples of the way in which he is always trying for new effects, but is not always successful. "Lytes Cary: Restoration," by Mr. CHARLES E. PONTING, is so good a restoration that one cannot tell what is new and what is old, so well has the character of an old west-country manor-house been preserved. Mr. EDWARD J. MAY'S "House on the Hindhead, Surrey," is like Mr. MAY'S work in general—quiet and excellent, with its tile-hung first floor and tile roofs. "Great Roke, Witley, Surrey," by Messrs. H. T. BUCKLAND & E. H. FARMER, is a big house and a good example of the manor-house type of mansion.

"The Hall, Putteridge Bury, Herts," by Messrs. ERNEST GEORGE & YEATES, is an interior of the character with which the President of the Institute has made us familiar. "The Knoll, Leicester," by Mr. WILLIAM H. BIDLAKE, is twice shown and is a good red brick and stone house of Tudor type, thoroughly typical. "A Country House," by Mr. J. E. DIXON SPAIN, is a quite modern twentieth-century design, completely an antithesis to Mr. BIDLAKE'S work, symmetrical and quaint in its use of rough-cast and brick. Mr. DUDLEY NEWMAN'S "Design for the Restoration of Fulbourn Manor, Cambs.," is a coloured perspective of a quite remarkable house, interesting both in plan, in grouping, and in detail. "Tuesly Court, Surrey," by Mr. E. GUY DAWBER, is an example of a building of local stone with tile roofs, brick dressings and chimneys that is quite refreshing.

Mr. REGINALD T. BLOMFIELD'S "Whittington, near Great Marlow," is a stately red-brick house with a central composition in stone of pediment and pilasters in typical English Renaissance manner, the central note being carried into the red brick portion of the building by stone quoins &c. Messrs. SILCOCK & REAY'S "Churchill Cottage Homes, Somerset," is a charming group of almshouses round three sides of a quad. "Worplesdon Golf Club-House," by Mr. ARTHUR A. MESSER, is a one-storey group of buildings with a picturesque roof treatment, eminently suitable for its purpose.

Mr. JOHN BELCHER'S "Lew House, Bampton, Oxon," and "Tatmore Place, Herts," are pictures of a prevailing greenish tone of which the buildings are almost too unimportant a part. Architects' illustrations of their designs are usually too much building and too little else to be pictorial. In attempting to avoid this fault Mr. BELCHER'S draughtsman has rather gone to the opposite extreme. "Ardenbrun Place, Surrey: the Entrance Porch," by Mr. ERNEST NEWTON, is a good piece of richly-treated detail in stone, the central feature apparently of a red brick building. "Headlands, Limpsfield," by Mr. ARTHUR KEEN, is at first sight a house without windows, but on a second glance one realises that it is the northern aspect. The use of gables without windows in them is, though not strictly defensible, a picturesque treatment of roofing that would otherwise have been rather awkward to plan without a considerable expanse of flat. "Twelve Cottages, Erskine Hill," by Mr. W. HENRY WARD, is a group of small houses at Hampstead for the Co-partnership Tenants, Ltd., and an interesting example of what can be done to infuse artistic design into what otherwise is but a piece of speculating builder's work.

ARCHITECTURE: ITS TRUE PRINCIPLES.—XI.

By R. OWEN ALLSOP.

THE POWER OF SIMPLICITY.

THIS is putting us right in domestic architecture. The sense to perceive that all that is affected, assumed—all that is not *perfectly natural*—has been the notable advance made in modern work. The works of our most respected present-day architects are characterised by the disappearance of sham—sham purpose or material, or method. Simplicity insists that no style should be followed for the sake of its characteristics.

Simplicity cannot lessen the need for brainwork. It rather makes this more urgent. The spirit of simplicity may be likened to order in its origination out of disorder. The disorderly heap is complicated, work is required to produce a simple state of things. To be simple is to be natural, and once this great truth is lost sight of, a world of difficulty has to be faced in recovering the true way.

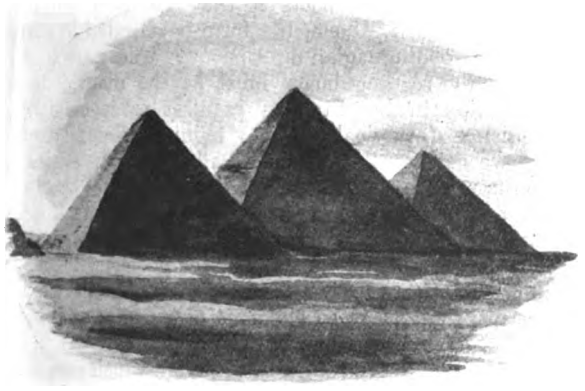

FIG. 25.—THE PYRAMIDS.

Simplicity is always effective, for the reason that the main theme, motive, or idea is kept clear. The greater the thing the greater the simplicity—the plain spherical (practically) world, the broad ocean, the round moon, the sun, the star points, the impressiveness of the trackless desert.

The demands of simplicity require that, of two ways choose the most straightforward. It is not, as we have endeavoured to show, that simplicity does away with or in any way is a substitute for brain work. It is rather its outcome. The way of simplicity is lighted by the lamp of truth, so that RUSKIN does well to treat rather simplicity as an effect than a root cause or principle. Nevertheless, one may be complex and complicated without dishonesty or sham, so that it is just as well that the nature of simplicity in architectural design and composition should be a little investigated on the lines assumed—that it may be designated a root principle or law.

Simplicity in massing and grouping is always pleasing, and it is so because it conveys a sense of straightforward honesty. The reverse impression attends greatly varied and complicated massing. The highly involved parts of many Eastern compositions are suggestive often of weirdness. Simplicity of plan suggests a clear head, arising doubtless from an impression of the presence of a high sense of order. It requires the exercise of much thought, if practical service is to be satisfied as well as æsthetic effect. Patching on "anyhow" is not simplicity—unless it be the simplicity of imbecility. The quality of simplicity is as pleasing in the building as in the man—to know the purpose and intention clearly, instead of being mystified and rendered suspicious by concealment, suggestive of underhand motives and ulterior unrevealed designs. Simplicity is correlative of, and leads to, unity, supposing a single eye and pureness of intention.

There is nothing about this principle, or attribute, of simplicity that induces tameness and insipidity, neither is it opposed to novelty and originality. Quite the reverse; if any practical service requires a novel arrangement not in accord with conventional treatment, let the opportunity be made the most of whether or no it seems orthodox. It is depressing to think of the many wasted opportunities attending compositions that would have secured novel and striking effects had the designer followed the suggestion thus thrown in his way. Yet he generally wipes out this chance because, forsooth, it is not in accordance with what others have done under similar circumstances and conditions. The law of simplicity says, "Be natural"—that is, take your opportunity—do what is required and do it boldly. Accept the course of events; follow up the chain link by link. It is only as this is done that perfect natural method is secured; and to be natural is to be simple.

We know what the simple roof mass has done for recent architecture. In the lines of main and secondary roofs lies the cause of much architectural effect. The mole-heap principle of packing on roofs here and there is the outcome of an ill-considered rambling plan, is not simplicity; it is rather barren nakedness of thought and idea and lack of trouble to simplify main outlines or plan, and of general mass arrangement. It is good to simplify roofs both for constructive reasons and for artistic effect. In all cases the demands of simplicity are that four parts shall not be arranged where all purposes are supplied by three—that is to say, that there be no needless multiplication of parts. This is in accordance with the requirements of good practical planning—that the various rooms and apartments required may be formed into the minimum number of masses, each mass as compactly arranged as possible. A plan must be compact, as distinct from rambling, and masses of building must be compact as distinct from the "happy-go-lucky" in their general relation the one to the other.

The motto of the Architectural Association is good so far as it goes, but it suggests PILATE'S question, and, further, "What is beauty?" In matters of architecture, perhaps, we need not greatly puzzle over the nature of truth. The ways of deception are so very apparent that all the main elements of building truly are, generally speaking, self-evident, and he must be very dead indeed to all sense of fitness who cannot nowadays avoid designing and construct that which is essentially false. The essence of deception is the intention to deceive. Therefore one must go very far indeed out of one's way to

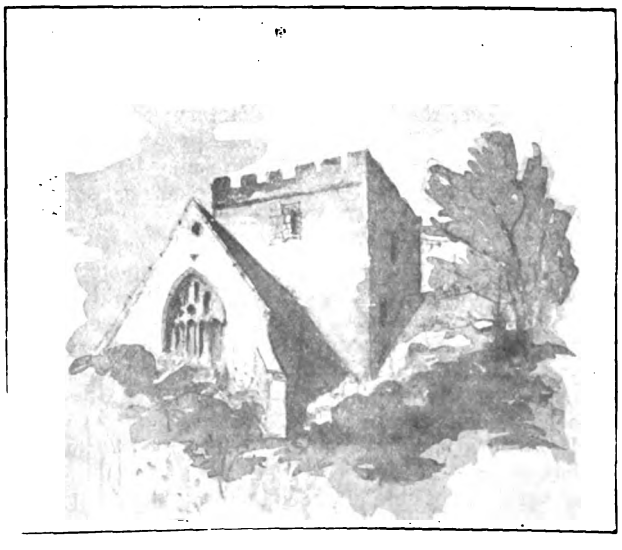

FIG 26.—POYNINGS.

create in a building the truly false. The simple design can never deceive. Truth is the first essential of simplicity—for simplicity is rather a compound of other attributes or quantities.

There is always this one satisfactory attribute to a natural design—it cannot offend; offence comes from affectation. The affected design cannot but displease equally with the affected person. Neither appear what they really are.

Digitized by Google

The advertisement artist knows—better than the architect apparently—that that which most powerfully attracts the eye is not elaboration of design, but the simple object—circle, square, or diamond. The cube is ever old, but always new. From the same fundamental cause the Pyramids hold the eye. The simplicity of mass of an old village church, such as Poynings, Sussex,

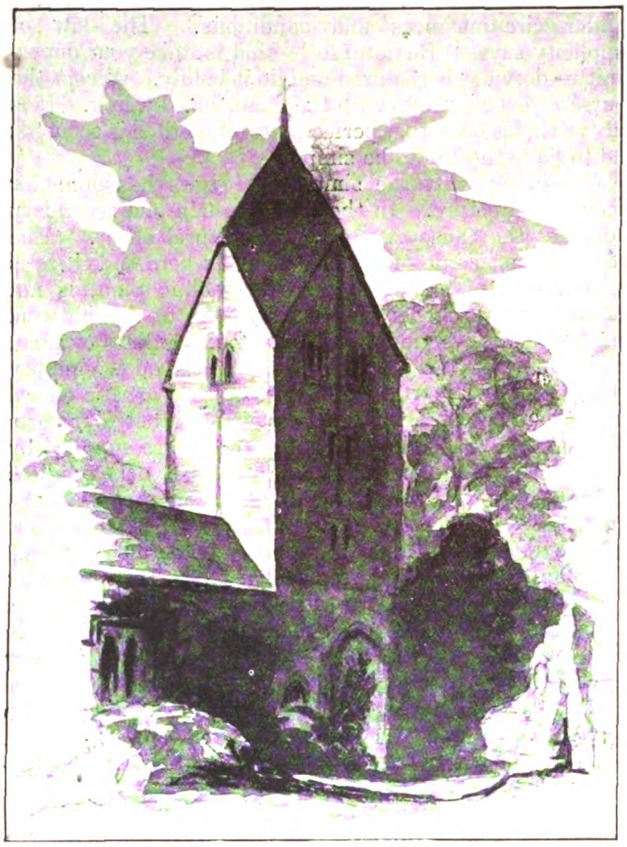

FIG. 27.—SOMPTING.

ensures dignity of effect. The tower of Sompting Church commands our respectful attention, where, often, elaborate form may repel. Against the north transept of St. Nicholas, Caen, is reared an object that powerfully arrests attention, because capped with a simple, elemental form of geometry—the cone.

It might reasonably be argued, in view of the stress laid on the necessity for geometrical simplicity of mass, that, therefore, the bald, square factory, the plain brick mill, barn, or skyscraper, must constitute the most excellent in architecture. In all these may be found that which may, in one view, be termed geometrical simplicity of main mass.

The suggestion, however, is not that the bald, naked cube, or other rectangular figure of solid geometry, should necessarily appear as such, but that they should form the basis or framework, so to speak. We may feel assured that, in one sense, it is this geometrical simplicity of the factory and like building that is the main source of their offensiveness and the prime cause of what we usually term hard, engineer's architecture.

If it were literally true that what we require is to exhibit a plain geometrical solid form, there would be little variety possible in architecture, since all would produce simple rectilinear and rectangular or other elemental forms of geometry, giving plain, hard outlines. Our view is that the geometrical basis should be to more elaborate architectural form, that which the frame is to the picture; to the end—for one thing—that the variety and play of form, in minor parts, should be enhanced by the simplicity of the skeleton mass; for, whatever Eastern taste may indicate, we here full well understand that highly varied curvilinear form in main masses vulgarises like forms employed in subordinate parts. That is to say, onion and bulbous domes and curved complexity of outline in main masses detracts from the value —as contrasted enrichment—of curvilinear outline in details. This is sufficiently self-evident, and it is not necessary to journey East to find multitudinous examples of congealed discord of this nature.

The severe rectangularity of a picture-frame enhances the value of varied and broken lines and surfaces in the picture. It might possibly be argued by the uninformed that what we require as frame for a picture of broken light and shade and line would be something to "harmonise," and least of all severe rectangularity and squareness. The truth, we know, is the other way about. Similarly, our view holds that the basic form of a building being square and rectangular, or otherwise geometrically regular and simple, this, in three-dimension matters, sets off as contrast and relieves more ornamentally varied form. The comparison—contrast—between picture and frame concerns matters of two dimensions; hence, in solids, the contrast—comparison—must be between forms of three dimensions. If we carve a small shamrock form on a similarly shaped solid trefoil mass, the smaller is killed by the larger; whereas by cutting the form on a plain cube we have the full value of relief and contrast. What boots it that we have delicately voluted capitals if, above, the form is repeated in coarse scrolls of Brobdingnagian dimensions? There are several reasons why rectangularity must be the main form of mass architectural. Stability requires perpendicularity. Convenience (practical service) requires rectangularity. Hence we get parallel, vertical walls and right angles at the commencement from (1) the necessities of practical service and utility, and (2) from the requirements of well-building—the scientific side of architecture. Again, it may be laid down that the simpler the geometry the more sublime the effect; for we may truly consider the simple figures of geometry to be elements of eternity, or at least to have been predestined from the beginning.

That principle of architectural design which rules that effect should be obtained by decorating construction, as distinct from constructing ornament, we all at this time admit as sound and far-reaching; but there is possibly a further rule—that we should enhance and render inter-

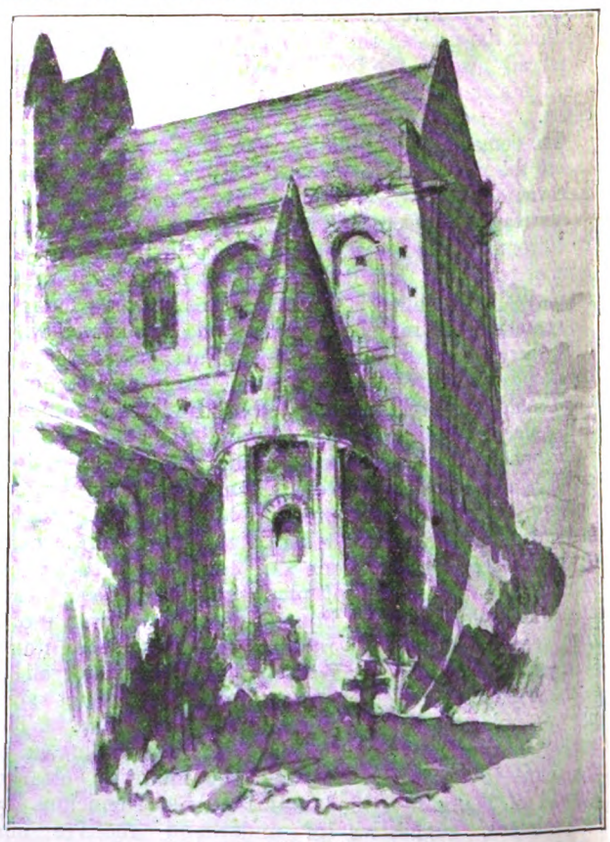

FIG. 28.—ST. NICHOLAS, CAEN.

esting and marked the geometrical basis. Crudely, this principle is exemplified in the practice of illuminating buildings, as where rows of lights run along cornices and round pediments, and in practical architectural design by putting piers at angles and cornices along upper edges. It is the idea that seems to impress us in the simplicity of a city lying "four-square," yet aglow with emerald,

Digitized by Google

sardius, and topaz. If a façade were primarily broken into varied masses, the row of buttresses could be vulgarised, whereas, breaking out of a regular superficies—the straight wall surface—they are enhanced by contrast. The simplicity of the geometrical basis here stands, in a sense, as the plain frame to the varied picture. The main idea seems to be to preserve the geometrically regular mass form. It may be broken into, as by a great recess, or added to, as by a portico, but the great lines—whether or no such lines are actually presented to the eye—should be preserved. Buttresses at angles may hide the cubical or other rectangular mass, and divisions break up great *surfaces* and small, so that the original geometrical framework practically disappears. The idea, roughly here expressed, seems to suggest that which is the essence of the principle: to break up the geometrical harshness and baldness, not by destroying the fundamental basis, but by subordinate additions and subtractions. In the beautiful campanile of St. Paul's Cathedral we are impressed by the simplicity of the geometrical basis and the regularity of main masses. The elemental forms are simple—the square and circle primarily; and there is a bell at the summit. Yet they do not appear in their baldness, being softened and toned by subordinate parts. One cannot look up at the belfry stages without observing the elegance that arises from contrasting (by position) and emphasising—as by bold cornices and the like—varied geometrical forms themselves quite simple. For all regular, rectangular, and cylindrical forms, however proportioned, must be considered simple and elemental, the simplicity varying only in degree.

Stable construction is necessarily based on mathematical considerations. Geometry is based on mathematics. Hence, decorating construction and decorating geometrical form, in architecture, are ideas having much in common.

(To be continued.)

THE CONCRETE INSTITUTE.

THE fifth general meeting of the Concrete Institute was held at the Royal United Service Institution, Whitehall, on May 27. Mr. F. E. Wentworth Shields, M.I.C.E., the chairman, in opening the proceedings, said that he had to announce that Mr. Hatch was unable through illness to preside. The membership of the Society had now reached the satisfactory number of 740. The continued growth was an indication that the good work accomplished by the Institute was becoming more and more recognised by the various professions. Mr. H. K. C. Bamber, F.C.S., then read a paper entitled:—

Some Notes Relating to the Setting of Portland Cement, with Description of Methods Adopted for Regulating the same.

The author began by stating that his object in writing the paper was to give to the members of the Concrete Institute a short *résumé* of some of the results of research work in this direction done by manufacturers and others, more especially as applied to the more modern methods of manufacture.

He purposely gave the practical side of the question the pride of place, as the interests of the members of the Concrete Institute, and, in fact, all users of cement, were more concerned with this branch of the investigation than with the other. It mattered little to them what the exact formula might be representing the composition of the ingredients and their combination in the finished product so long as they had at their command a material which could be used under all conditions of their work, and positive information from the practical results of competent investigators in this field of inquiry as to the best methods to be adopted by the engineer and other users to insure successful work in the sometimes difficult conditions under which this work had to be carried out.

He did not propose to express any new theories, but in order that it might be seen how indefinite the present real scientific knowledge of this difficult subject was, and what insufficient and contradictory data the cement manufacturer had at his command when embarking on any practical experiment based on scientific theories, Mr. Bamber shortly referred to those which existed, and were most accepted at the present time.

It was well known that for the best cement the total percentage of lime (CaO) present, as found by analysis after decomposition of the various silicates and aluminates by solution and subsequent separation, was confined to very narrow limits—*i.e.*, 63.5 to 65 per cent. The amount of silica (SiO_2) varied from 21 to 22.5 per cent., and alumina (Al_2O_3) from 5 to 6 per cent., so that whether the ratio of lime to silica was calculated on a percentage basis or in accordance with chemical equivalents, it approximated 2.8 parts lime to 1 part silica, the formula for which, without assuming any definite combination, might therefore well be written as $3CaO \cdot SiO_2$, leaving approximately the lime required in combination with alumina to form dicalcic aluminate, and any attempt to vary this ratio to any extent resulted in a material which had not the good properties of, and could not be designated as, a true Portland cement.

The percentage figures he had mentioned of 63.5 to 65 per cent. of lime might appear to many who were accustomed to the old specifications for cement, placing a maximum of 61.5 per cent. for lime, to be high, but many analyses of pure clinker taken from such kilns as were used for the old methods of manufacture, and which were presumably producing cement within that apparently low limit, showed that for years the higher figure had been the percentage in all good cement clinkers, the actual fact of its presence in such quantities in the ground cement in part being cloaked by the accidental introduction of extraneous foreign matter derived as an uncombined residue from the fuel used for calcination.

These facts were mentioned, as they had an important bearing on the setting properties of cement.

Like the constitution of Portland cement, the theories as to the setting were also somewhat vague and uncertain; but it was generally assumed that the action was brought about firstly by the hydration upon the addition of water and subsequent crystallisation of the calcium aluminates present, which occurred with great rapidity, constituting what was known technically as the "initial set," causing cohesion of the mass of cement and the intermingled aggregate. This was followed by the hydrolysis of the calcium silicates, the latter being slowly decomposed and broken down into the more simple form of mono-calcium silicate, with the consequent liberation of calcium hydrate ($Ca(OH)_2$), which being in excess of that required to form a saturated solution partially crystallised out—this cycle of operations continuing over long periods during the hardening of cements.

These, then, were the hypotheses, correct or incorrect, which guided the cement manufacturer embarked on a field of investigation, or with which he endeavoured to explain the various phenomena which presented themselves from time to time during the course of manufacture.

The time allowed for consideration of these matters would not permit of a complete exposition of the many problems that confront the manufacturer, and it was proposed, therefore, on this occasion, to deal only with some of the points that arise in connection with the retardation of the setting time in order that the latter might be brought within reasonably controllable limits, and to endeavour to explain the irregularities that were sometimes found when testing the setting time and the soundness of present-day Portland cements.

A thoroughly well-made Portland cement clinker, ground to normal fineness, was always very quick-setting, almost equal to that of plaster of Paris, but this property of rapid-setting could be somewhat delayed by mixture of other foreign substances, as was done accidentally until recent years, and in fact yet continued, with cement manufactured on the intermittent kiln system, now being rapidly superseded. By this method dry material of uniform and correct composition was calcined by mixture with from 40 to 45 per cent., or even more, of its weight of coke and coal, the ash from the fuel—about 12 to 15 per cent. of the weight of the fuel used—remaining mixed up with the calcined clinker. In most cases this foreign matter alone had the effect of prolonging the setting time some few minutes, but portions of the clinker removed separately and free from the fuel ash when ground to powder set almost instantaneously upon the addition of water, with disengagement of considerable heat due to the rapid chemical action.

It was difficult to satisfactorily explain why the admixture of the fuel ash should have the effect of retarding the setting time somewhat, unless it was that it contained an amount of sulphates derived from the oxidised sulphur compounds originally present in the fuel used, and these sulphates having a similar effect on the cement as the addition of a similar amount of gypsum—or it might be that owing to the less perfect burning of cement in the

Digitized by Google

past cement always contained free lime in the amorphous, as distinct from the crystalline condition—this lime was quickly dissolved in the water used for gauging, which, becoming saturated, prevented the solution of the calcium aluminates, and thus somewhat retarded the set.

During recent years, and upon the introduction of new methods, more particularly that of the rotary kiln, none but this pure character of clinker was produced, containing practically no free lime in the amorphous condition—the system being such that the ash from the fuel, the latter in quantity being in itself at least 33 per cent. less, to a very large extent passed away with the effluent gases from the kiln. This also applies largely to the sulphur compounds in the raw material and coal, which, being decomposed, passed out of the kiln as sulphurous acid with the other gases. The clinker thus produced was practically pure, and resembled those portions of picked uncontaminated clinker from the intermittent kiln previously referred to, and, like that, had, when finely ground, an almost instantaneous set, and with a lime content on analysis in both cases ranging between 64 and 65 per cent. It was thought that cement manufactured by the rotary process had a quicker initial set when untreated with any addition for the purpose of retardation than had the cement made by the older process; but this had been found to be an entire fallacy, since it was found that the pure uncontaminated clinker from an intermittent kiln was equally as quick setting as the pure clinker from the rotary kiln, the similarity being cloaked by the presence of the foreign matter from the fuel in the older process cement.

The realisation of these facts was not apparent in the early days of the more modern methods, and the manufacturer was faced with what appeared to him at first to be a new difficulty, whereas in reality it was the obvious result of the more careful production of a pure material, which he had been accustomed formerly to manufacture accidentally in a more or less contaminated condition. In ignorance of the above facts it was thought that perhaps the rapidity of the modern manufacturing process—more particularly the cooling down from the higher ranges of temperature of the calcined clinker, which was accomplished in a few minutes after reaching the maximum temperature—might be the cause of the apparently more chemically active condition of clinker manufactured by the rotary process; and very elaborate and costly experiments were carried out, extending over a long period, in which the calcined clinker after passing the clinkering temperature was kept at a red heat for a considerable time before final cooling, imitating, it was thought, the slower action of the old intermittent kiln process.

Unfortunately—like many others—this experiment, although carried out on a practical and commercial scale, either through the difficulty in regulating the supplies of clinker to insure a steady temperature of cooling, or through mechanical difficulties which the operation presented, was of a negative character.

Previous laboratory experiments in this direction had given great promise that more useful results might have been obtained, and undoubtedly indicated that during the calcination of cement clinker there are critical points of temperature of great importance, and well worthy of the careful study of the scientific specialist.

Experiments were also carried out to test the concentrated action of carbonic anhydride upon these various aluminates, this being the principal ingredient in the atmosphere which, together with water, brought about the natural process of aeration of cement. It was found that the aluminates containing the higher proportion of lime were less affected by this treatment with CO_2 than the lower aluminates, which it was thought might be the explanation why rotary cement was less affected by exposure to the atmosphere than cement made in intermittent kilns.

A very considerable amount of research work was done under the author's supervision in connection with the properties of the various calcium aluminates, to which the quick setting property of Portland cement was attributed. As already explained, it was thought that the more rapid cooling of the clinker probably had some chemical or physical effect on the aluminates present, and in order to test this theory the dicalcic, tricalcic, and tetracalcic aluminates were synthetically prepared in order if possible to test their setting properties individually when rapidly or slowly cooled from the state of fusion.

Unfortunately, such investigations were replete with difficulties, and it must not be forgotten that in examining these isolated components of cement their assumed properties when in a pure state might be entirely altered by the presence of other ingredients in cement reacting one upon the other. On the whole, the results in this line of research were of a negative character, but the author mentioned this series as one of many such experiments carried out to indicate the highly scientific class of investigation the cement manufacturer was prepared to undertake to obtain a further knowledge of the properties of the material the manufacture of which was under his control.

Attempts had also been made to reduce the quantities of aluminates present by adjusting the composition of the raw materials, by increasing the silica content at the expense of alumina; but here again only partial success was met with, as it would appear that even small proportions of calcium aluminate present were sufficient to cause a very rapid initial set of the whole mass—in fact, as far as the author was aware in no case, even where the raw materials were such that the calcined clinker contained a high percentage of silicates and a low percentage of aluminates, was the initial set of such cement, untreated with retarders, other than very rapid—in fact, almost instantaneous.

In order to avoid the necessity for the addition of gypsum to the calcined clinker, which until water was added to the cement was present only as a mechanical mixture, it was thought that this addition might be made to the raw material previous to calcination, during which operation it might become evenly incorporated with the whole mass of clinker, but in practice this was found to be quite inoperative as at the maximum temperature of the kiln in the presence of silicates, &c., gypsum incorporated with the raw materials was decomposed, the sulphuric anhydride (SO_3) being evolved and passing out of the kiln with the other gases, the remaining life (CaO) combining with the silicates (clay); the added calcium sulphate in this case only having the same function as the calcium carbonate present, which gave up its carbonic anhydride (CO_2), which escaped from the kiln, leaving the remaining calcium oxide (CaO) to combine with silica and alumina (clay).

Various other suggested methods of prolonging the setting time of cement without having recourse to the mechanical addition of retarders to the finished cement had been attempted, such as the injection of solutions of the alkalies and alkaline earths, and such like, upon the hot clinker during its passage through the cooler, but all these had met with only limited success, the results obtained being in many cases evanescent, and in others creating further mechanical difficulties in the grinding of the clinker, which rendered such processes physically and commercially undesirable.

At the end of the nineteenth century practically all the cement manufactured in the United Kingdom and in Europe was produced by the old method of calcination in intermittent or somewhat similar kilns, the product being a clinker having various degrees of hardness, ranging between the material thoroughly calcined at a temperature above 2,800 deg. Fahr. (at which temperature a thorough chemical combination has taken place), and the material technically known as "half-burn," which latter was practically the raw material from which only the carbonic anhydride of the chalk or limestone and the water of hydration and organic matter of the clay had been expelled. Now it was quite easy to realise, seeing the very complex character of the chemical combinations which were thought to take place at the true temperature of calcination, how difficult, and, in fact, almost impossible, it must be to determine a formula which will correctly represent the chemical composition of even a uniform raw material calcined under such a wide range of temperatures as that represented by 2,800-900 deg. Fahr., at which latter temperature the volatile matters from the raw materials were expelled.

It was equally easy to realise that the physical conditions, and therefore the setting properties of the atoms forming this heterogeneous mixture, must be of a very varying character, depending largely upon the relative proportions of the heavy or more lightly burned clinker, or that of an intermediate character, present in the mass as removed from the kiln; the more heavily burned portions were considered the most valuable, more especially those portions of clinker which had not been contaminated with or fused by contact with the siliceous matter contained in the ash of the fuel; and the product of the present-day rotary kiln, calcined in small particles at a uniform temperature, and in the absence of fuel ash, consisted, as one would expect, almost entirely of this pure clinker. The only methods known to the ancients of retarding the setting time of this heterogeneous mixture of silicates and aluminates was by exposing such cement after grinding to long

Digitized by Google

periods of aeration, or by the addition of gypsum in one form or other.

The first process was only successfully applicable in the absence of added gypsum, and the effect of prolonged aeration of such cement was the absorption by the uncombined lime and the loosely combined silicates and aluminates, &c., of water derived from the moisture in the atmosphere, and subsequently carbonic anhydride from the same source. In this manner a considerable quantity of the material became carbonated and inert, depriving the cement of a not inconsiderable portion of its former chemical activity and thus causing a prolongation of the setting time.

It would be seen that such method must be most imperfect in its action and required a considerable length of time to enable the moisture and the carbonic anhydride in the atmosphere to find its way into the interior portions of the heap, by which time the outer portions would be considerably over-aerated and become practically inert.

It would seem that the action of the atmosphere was confined to the loosely combined or lightly burned particles of the cement and that the thoroughly calcined particles were little affected by exposure to the atmosphere at normal temperatures, and this experience seemed to be confirmed from the fact that cement manufactured by the rotary process, producing the pure clinker, when ground without treatment or additions to retard the setting time, would retain its original quick-setting property unimpaired for long periods when stored in bulk. Instances of this had occurred where cement having an almost instantaneous set at the time of manufacture had retained this property when kept in bulk, but otherwise exposed to the atmosphere, for a period of two years.

It would be seen from this that the old method of simple aeration in bulk to retard the setting time could not be applied with any degree of the former success to the product from the rotary kiln, and this would also seem to be evidence that the cement manufactured by the more modern process was of a more stable and reliable character than that formerly put upon the market. A cursory examination of the clinker produced by the two methods would, even to the uninitiated, be sufficiently convincing on this point.

In view of the fact that this simple method of aeration in bulk could not be successfully applied to cement manufactured on the new system, many attempts were made to accomplish the most important part of natural aeration, i.e., the absorption of water, by artificial means, such as passing the ground cement through a moist atmosphere, or by blowing moist air through the cement in bulk. These methods, however, were not found to be wholly successful, firstly, from the physical and mechanical difficulties which presented themselves by reason of the partial setting of the finest portions of the cement, with the consequent blocking of any apparatus used for the purpose, such as revolving drums, distributing discs, conveyor screws, and scrapers, and the like; and secondly, in the author's opinion, for the much more important reason that, in order to accomplish the desired result in a short space of time, it was necessary to submit the cement manufactured by the rotary process (all of which consisted of finely reduced particles of the pure calcined clinker) to a moist atmosphere at a comparatively high temperature, as distinct from the normal temperatures under which all the previous attempts at artificial aeration had been carried out.

In order that this might be accomplished, and the cement submitted to a moist atmosphere at a high temperature, in which the action of the water vapour upon the particles of clinker might be rapid and effective, a process was introduced in which advantage was taken of the peculiar construction of the mills chiefly used for completing the reduction of the cement to a fine powder in enclosed revolving cylinders, known in the trade as "tube mills," which contained as their grinding media a heavy charge of steel balls or flint pebbles.

(To be continued.)

THE NATIONAL GALLERY.

THE report of the Director of the National Gallery for the year 1908 was issued last week.

The most important purchase was "A Family Group," by Frans Hals. This was bought from Mr. A. H. Buttery, acting on behalf of Lord Talbot de Malahide, for 25,000*l*. The vendor was willing to accept half the purchase money in instalments spread over three years, and H.M. Treasury agreed to recommend a supplementary vote of 12,500*l*. towards the purchase on condition that the normal annual grant-in-aid of 5,000*l*. should be suspended for the year 1909-10, and that the needed balance of 2,500*l*. should be raised by private aid. Subscriptions to the close of 1908 amounting to 2,621*l*. have been received, and it is hoped that in view of the forestalment of the next two years' grant-in-aid further help towards this important purchase will be forthcoming.

Two portraits by Alfred Stevens were purchased from Mr. Gamble for 250*l*. each. The "Portrait of Jacqueline de Bourgoyne," by Jan Gossart (1470-1541), Flemish School, was purchased from Messrs. Agnew, who bought it at the Gauchez sale in Paris and ceded it to the Trustees without profit for 2,300*l*.

Since the issue of the last report the Trustees have received a further sum of 5,103*l*. 17*s*. on account of capital under the terms of Colonel Temple West's bequest, making a total amount of 99,909*l*. 6*s*. 1*d*.

In 1906 a bequest to the National Gallery of a certain sum of money by the late Mr. C. E. G. Mackerell was announced, but, as the will was disputed by the next of kin, the case was referred to H.M. Treasury. During the past year a satisfactory settlement was made by the Solicitor to H.M. Treasury, and the Trustees received the sum of 2,859*l*. 9*s*. 11*d*. and were informed that there were further funds which would, on the determination of certain life interests, pass to the Trustees of the National Gallery. The interest only of this sum is available for the purchase of pictures.

Four works were bequeathed by Mr. Martin H. Colnaghi—viz. "Madonna, Child and Saints," by Lorenzo Lotto; "The Bohemians," by Philip Wouwerman; "Dawn," by Aart van der Neer; "The Bridge," by T. Gainsborough, R.A. In addition to the above, under the will of the late Mr. Martin H. Colnaghi, the Trustees of the National Gallery were made his residuary legatees, subject to the life interest of Mrs. Colnaghi, and subject to certain conditions as to the disposal of the testator's property. A portrait of this donor by J. C. Horsley, R.A., has been presented by Mrs. Colnaghi.

The nine following works of art were purchased for the nation by the President and Council of the Royal Academy of Arts under the terms of the Chantrey Bequest:—"The Gleaners Returning," by George Clausen, R.A.; "The Fountain," by Charles Sims; "A Pasturage among the Dunes. Pas de Calais," by H. Hughes-Stanton; "Old December's bareness everywhere," by J. Buxton Knight; "Marie Antoinette," by Miss Mary Gow; "Gold Lace has a Charm for the Fair," by Frank Dadd; "Ariadne" (sculpture), by Harold Parker; "Diana" (sculpture), by Bertram Mackennal; "A Foul in the Giants' Race" (sculpture), by Charles L. Hartwell.

Four of these pictures from the Chantrey Collection have, with the sanction of H.M. Treasury, been temporarily lent to the following institutions, in pursuance of a custom initiated by the Royal Academy, and in response to a general desire that they might be seen in the provinces before being finally housed in the National Gallery, British Art:—"The Fountain" to the Liverpool Walker Art Gallery; "A Pasturage among the Dunes" to the Royal Society of Artists, Birmingham; "The Gleaners Returning" to the Royal Museum and Libraries, Salford; "Gold Lace has a Charm for the Fair" to the Corporation Museum and Art Gallery, Leicester.

The two following pictures, purchased under the terms of the Chantrey Bequest in 1907, which were lent to the Liverpool Walker Art Gallery and the Royal Society of Artists, Birmingham, respectively, have now been returned and hung in the Gallery of British Art:—"The Rehearsal," by L. Campbell Taylor; "Runswick Bay," by Arthur Friedenson.

On the recommendation of the Trustees, the Lords Commissioners of H.M. Treasury have sanctioned the opening of both Galleries free to the public on all Sunday afternoons throughout the year from 2 P.M. until the hour at which the Galleries are closed on free weekdays in each month.

H.M.'s First Commissioner of Works announced last year that, by the gift of Sir Joseph Duveen, a new wing, comprising five rooms with other rooms below, would be added to the National Gallery, British Art, for the exhibition of the Turner Bequest. The National Gallery Board had been previously consulted, and had approved the removal of the whole of the Turner collection to this new building, with the exception of such pictures as should be needed sufficiently to exemplify this master in the representative British School at Trafalgar Square, including the two pictures which, in fulfilment of Turner's will, hang side by side with pictures by Claude Lorrain in the French School. The new rooms are

Digitized by Google

at the north-west corner of the existing building, and their construction is already well advanced. They are designed by Sir Joseph Duveen's architect in harmony with the architecture of the Tate Gallery.

In the course of the past year the removal of the temporary Vauxhall Bridge and the consequent levelling of the road in front of the Gallery made it possible to complete its approaches. The road now curves in to the foot of the steps; the garden has been enclosed with new railings and gates; and the part affected turfed, gravelled and supplied with seats.

The installation of electricity in the basement of the Gallery of British Art has been carried out, to the great convenience of the offices, refreshment room, &c., and for purposes of inspection.

The Gallery in Trafalgar Square was visited by 637,304 persons on the free days during the year, showing a daily average attendance on such days (209 in number) of 3,049. In addition to the above number, 58,156 persons visited the Gallery on the thirty-nine Sunday afternoons on which it was opened during 1908, showing a daily average attendance of 1,491.

On students' days (Thursdays and Fridays) 63,691 persons were admitted between January 1 and December 31, 1908; the admission fees (at 6*d.* each) amounting to 1,592*l.* 5*s.* 6*d.*, as compared with 1,448*l.* 10*s.* 6*d.* received in 1907.

The National Gallery, British Art, at Millbank, has been visited by 244,683 persons on the free days during the year, showing a daily average attendance on such days (206 in number) of 1,188. In addition to the above number, 47,107 persons visited the Gallery on the thirty-nine Sunday afternoons on which it was opened in 1908, showing a daily average attendance of 1,208.

The amount annually realised by admission fees at both establishments is devoted as an "Appropriation in Aid" of the Parliamentary Vote to the National Gallery.

On students' days (Tuesdays and Wednesdays) 40,123 persons were admitted between January 1 and December 31, 1908; the admission fees (at 6*d.* each) amounting to 1,003*l.* 1*s.* 6*d.*, as compared with 1,005*l.* 11*s.* in 1907.

The total number of students' attendances at the Gallery in Trafalgar Square on Thursdays and Fridays throughout the year was 17,630. Independently of partial studies, 654 oil-colour copies of the pictures have been made—viz. 357 from the works of fifty-eight old masters, and 297 from the works of twenty-three modern painters. Two hundred and twenty-two new students have been entered on the books during the year. The total number of students' attendances at the Gallery of British Art on Tuesdays and Wednesdays throughout the year was 7,301; and 392 completed copies of the pictures have been made in oil colours, eighty in water colours, and nine in pastel. One hundred and two new students have been entered on the books during the year.

ILLUSTRATIONS.

THE HAMBURG-AMERIKA LINIE OFFICES, COCKSPUR STREET, S.W.—DETAILS.

IN our issue of March 12 we published a perspective drawing of this building, together with a photograph showing the interior of the general office. The main portion of the ground-floor and basement is occupied by the Hamburg-Amerika Linie as offices; the remainder of the seven storeys is available for letting, being divided into suites according to tenant's requirements. The external bronze work, including the large panel with life-size figures over the entrance to the shipping office, was modelled by Mr. J. WENLOCK ROLLINS and cast by Mr. BURTON, of Thames Ditton. The sculpture in Portland stone on the façade (Bath Stone Firms) comprises two large figures in half pediments representing Germany and America, and a frieze of nine bas-relief panels across the curved lines of the bay windows, the subjects being the chief travel stories of antiquity. These were modelled and carved by Mr. W. B. FAGAN. The total cost of the work was about 50,000*l.* The contractors were the Waring-White Building Co., Ltd. The architects are Mr. ARTHUR T. BOLTON, A.R.I.B.A., and Messrs. STOCK, PAGE & STOCK, F.R.I.B.A., of Victoria Mansions, 28 Victoria Street, S.W.

COMPETITION DESIGN FOR CORNWALL COUNTY OFFICES.

WE publish to-day the perspective view and ground-floor plan of the design submitted in competition for the above building by Mr. EDWIN T. HALL, V.P.R.I.B.A., of 54 Bedford Square, W.C. The author interpreted the instructions to require an economical design, and therefore sought to obtain a dignified exterior without extravagance. It will be noted that the council chamber and all the committee and other members' rooms are on the ground floor, and so are all the offices of heads of departments. The committee and the members' dining rooms, &c., are placed in a quiet position away from the noise and bustle of general work, while they are close to the council chamber, and all could be used for conference rooms and for receptions. The future addition of the town clerk's department was arranged on the first floor, so that when erected the whole building would be a compact entity. The main staircase for public access to all the departments is arranged from a circular hall, while there are two staff staircases for intercommunication of departments and for ready access from all to the council chamber.

NEW CLUBHOUSE, JUNIOR SUDAN CLUB, KHARTOUM.

THIS building, which has recently been erected as a club house for junior Government officials, was formally opened on March 2, 1908, by the Governor-General, Sir REGINALD WINGATE, K.C.B., K.C.M.G., &c. The plan consists of a billiard room 27 feet by 18 feet, with reading room adjoining, and there is a wide verandah on the north side. The material is local red brick. The club occupies an excellent corner site on the Khedivial Avenue (close to the Gordon statue), and was designed by Mr. O. BEESTON HATCHARD, town architect, P.W.D., Khartoum.

DORMERS, BOVINGDON, HERTS.

THIS house, of which the illustration shows the entrance front, is now nearing completion on a charming site some ten acres in extent about 2½ miles from Boxmoor. The external walls are of 14-inch brickwork roughly rendered with cement stucco and whitened, the plinth, chimney stacks and dressings, and the forecourt walls being of red brick in varied tints; while the roofs are covered with sand-faced tiles. The accommodation consists, on the ground floor, of hall, dining and drawing room (all three opening on to the loggia), servants' sitting room, and the usual offices; on the first floor there are seven bed and dressing rooms, bath rooms, &c.; and on the top floor a large billiard or play room, with beautiful views therefrom of the surrounding country on all sides, also two bedrooms, bath room, box room, &c. An entrance lodge is also being constructed in connection with the house. Mr. WALTER E. HEWITT, A.R.I.B.A., of 22 Buckingham Street, Strand, W.C., is the architect, and Mr. A. TIMBERLAKE, of King's Langley, the builder. The perspective drawing was by Mr. SYDNEY W. DAVIS.

THE CIVIL HOSPITAL, KHARTOUM.

THIS building has recently been erected in Khartoum by the Sûdan Government—Captain M. RALSTON KENNEDY, R.E., D.S.O., Director of Public Works—at a cost of E25,000*l.* on a large open site on the Sirdar Avenue on the south side of the town. The material is hard white sandstone from the Gebel Auli quarries on the White Nile, with mouldings, string courses, &c., in cement. The arcade in the front elevation, and the verandahs roofed with Marseilles tiles at the back screen the main walls from the sun and render the large airy wards cool in summer. The operating theatre and sanitary blocks are lined with glazed bricks and tiles, and the building is fully equipped throughout with the most modern hospital fittings of English pattern. The fireproof floors of the wards, &c., are tiled, and the corridors and main staircase are in terrazzo mosaic. The hospital and accessory buildings are lit throughout by electric light, and the current is also utilised for fans in every ward. The key plan shows the accommodation provided. The hospital was built to the designs of Mr. O. BEESTON HATCHARD, town architect, Khartoum.

GATEWAY TO A STREET FRONT, GHENT.
From a Sketch by BANISTER FLETCHER.

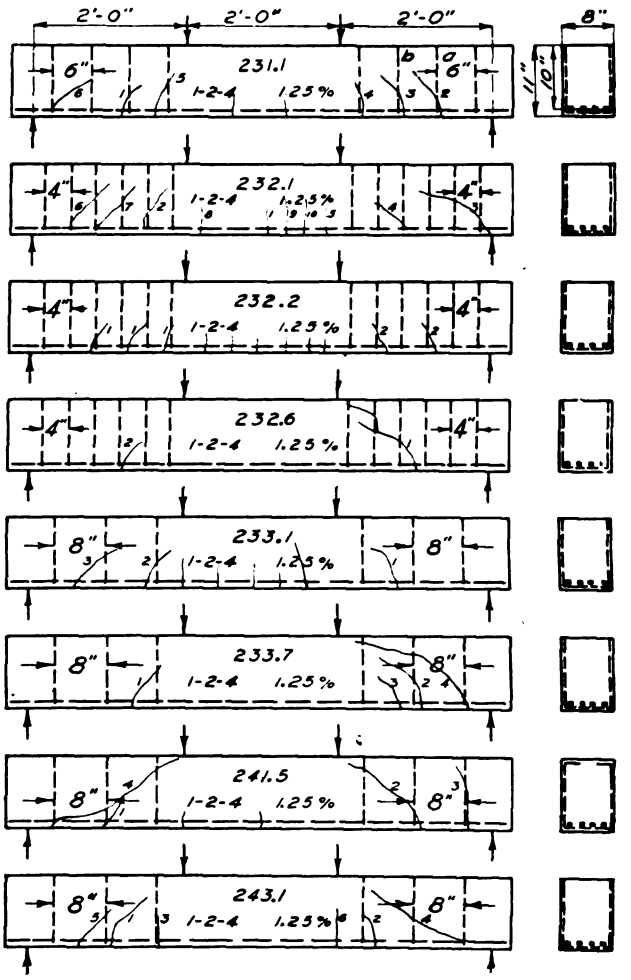
TESTS OF REINFORCED CONCRETE BEAMS.

(Concluded from last week.)

THE following are notes of the tests of beams with stirrups:—

Beam No. 231.1.—At 25,000 lb. diagonal crack marked (1) was noted 10 inches to left of left load. At 26,000 lb. cracks appeared in middle third and diagonal crack (2) was noted, and at 28,000 lb. diagonal cracks (3) and (4). At 29,000 lb. and 30,000 lb. cracks marked (5) and (6) noted at left end of beam. At 32,000 lb. metallic noises were heard and diagonal cracks continued to open. Maximum load, 33,000 lb. Load dropped to 14,900 lb., as ultimate failure occurred at (3) and (4); stirrup marked (*a*) broke, and stirrup marked (*b*) slipped.

Beam No. 232.1.—At 26,000 lb. vertical crack marked (1) appeared. At 28,000 lb. diagonal crack (2) was noted at left end and diagonal cracks (3) and (4) at right end. At 30,000 lb. diagonal crack (6) appeared. At 32,000 lb. crack marked (7) was noted at left end and vertical cracks marked (8) and (9) in middle third, and at 34,000 lb. vertical crack (10). At 36,000 lb. tension cracks in middle third were opening, diagonal cracks not opening much. Maximum load, 38,000 lb. Load dropped to 32,600 lb. failure occurring by tension in steel.



Beam No. 232.2. At 24,000 lb. numerous vertical cracks noted in middle third and diagonal cracks marked (1) at left end, but these did not open very wide. At 32,000 lb. diagonal cracks marked (2) were noted at right end. Maximum load, 40,300 lb. Failure occurred by tension in steel.

Beam No. 232.6. At 19,000 lb. a short diagonal crack marked (1) noted at right end at mid-depth of beam. At 20,000 lb. the above crack extended downward to bottom of beam and upward along fifth stirrup from end, a branch extending to load point. At 21,000 lb. crack marked (2) noted. Failure occurred by diagonal tension. Maximum load, 25,000 lb.

Beam No. 233.1. At 27,000 lb. a diagonal crack marked (1) was noted 21 inches to right of centre and extended vertically 6 inches. At 36,000 lb. a diagonal crack marked (2), 6 inches high, was noted 18 inches to left of centre of beam. At this load a vertical crack 5 inches long appeared under left load, tension cracks 4 inches long were noted 6½ and 1 inch to left of centre and a tension crack 3 inches high 3 inches to right of centre. At 41,000 lb. a diagonal crack marked (3) extended vertically 5 inches. At 43,200 lb. all cracks were opening. At maximum load, 43,300 lb. a tension crack 7 inches long noted 7 inches to right of centre. Failure occurred by tension in steel.

Beam No. 233.2. At 20,000 lb. a diagonal crack appeared 9 inches to left of left load and extended vertically 4 inches. At 28,000 lb. several vertical cracks were noted in middle third, and two diagonal cracks at right end. Diagonal crack noted at left end at load of 32,000 lb. Maximum load 34,700 lb. Failure occurred at right end by diagonal tension probably followed by slipping of bars. Middle stirrup at right end finally split out at near the maximum load on account of being too near the surface—about 1 inch centre to surface.

Beam No. 233.7. At 23,000 lb. a diagonal crack marked (1) noted which extended vertically 5 inches. At 24,000 lb. a diagonal crack marked (2), 7 inches high, noted. At 26.000 lb. diagonal cracks marked (3) and (4) appeared and extended vertically 4 inches. The other cracks were opening up at this load. At 27,000 lb. the cracks were lengthening. At 27,200 lb., the maximum load, diagonal crack marked (4) opened and extended to load point. Load dropped to 22,000 lb., failure occurring by diagonal tension with slipping of stirrups.

Beam No. 235.1. At the maximum load of 14,500 lb. a diagonal crack 6 inches high appeared 13 inches to left of left load. Load dropped gradually, and at 13,000 lb. the crack was opening up rapidly toward load point.

Beam No. 235.5. Mixture was lean and concrete seemed poorly rammed at bottom. Failure occurred by diagonal tension. On one side the diagonal crack was observed at third stirrup from load. This stirrup was afterward found to be broken. Maximum load 6,100 lb.

Beam No. 241.5. Stirrups bent in at top. At 18,000 lb. diagonal cracks marked (1) and (2) noted, (2) extending toward load point at 27,000 lb. At 22,000 lb. a crack 10 inches long marked (3) appeared. At 26,000 lb. a crack marked (4) was noted at left stirrup 2 inches above bottom of beam, extending to second stirrup from left end, and from there to load point. Maximum load 32,300 lb., failure occurring by diagonal tension.

Beam No. 243.1. At 26,000 lb. diagonal cracks marked (1) and (2) appeared. At 30,000 lb. a diagonal crack 6 inches high marked (4) noted at right end, 13 inches from load. At 32,000 lb. the cracks at left end were opening wider. At 34,000 lb. a diagonal crack marked (5) was noted 16 inches to left of left load and extended upward 6 inches. Maximum load 44,300 lb., failure occurring by diagonal tension.

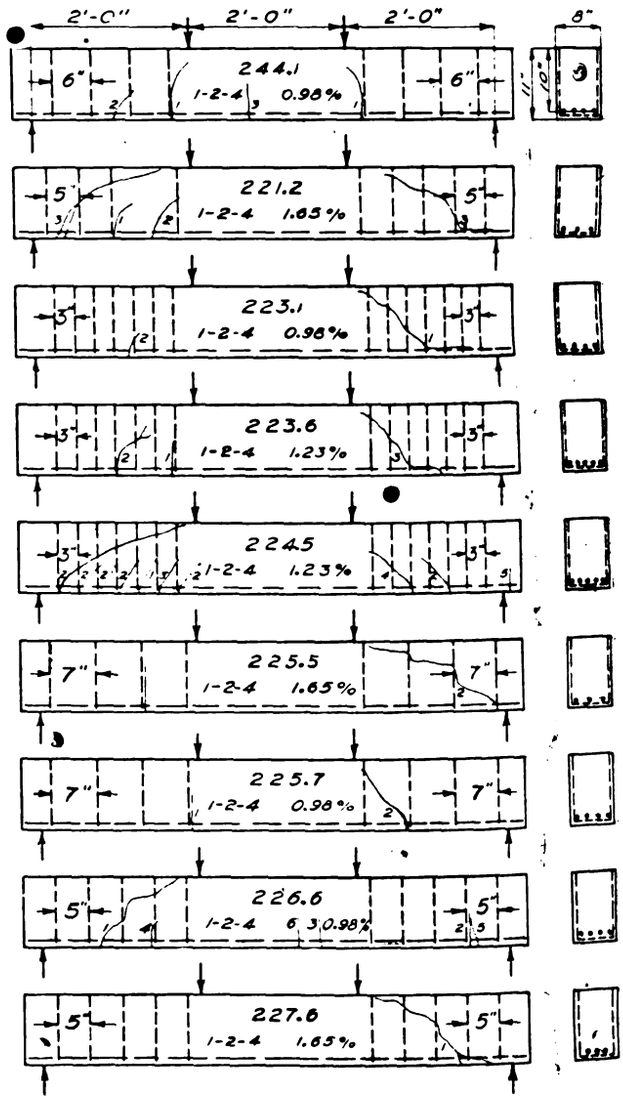
* Tension failure.
† Appearance indicated poor concrete.
‡ Failure at the end not having stirrups.
§ Load applied at a single point 2 feet from one support.

Beam No. 244.1. At 18,000 lb. vertical cracks 4 inches long marked (1) noted 2½ inches to right of right load and 2½ inches to left of left load at stirrups. At 22,000 lb. a diagonal crack marked (2) appeared 11½ inches to left of left load and extended vertically 4½ inches. At 23,700 lb. the crack at north end was opening wide. At 24,000 lb. a vertical crack marked (3), 6 inches high, was noted 3 inches to the left of centre. Maximum load 24,100 lb. Tension crack marked (1) to left of load opened wide after the maximum was reached.



Beam No. 271.6. At 12,000 lb. vertical crack 5 inches long was noted 5 inches to right of right load. A short diagonal crack was also noted in lower third of beam on opposite side 7 inches to right of right load. At 13,800 lb. failure crack appeared suddenly, starting at right end 7 inches inside the support and extending to within 4 inches of load. The expanded metal web was not sufficient to give much resistance.

Beam No. 221.2. Three stirrups at right end were showing at surface. Concrete was poor. At 22,000 lb. a diagonal crack marked (1), 4 inches high, was noted 12 inches to right of left support. At 24,000 lb. diagonal crack 5 inches high marked (2), 6 inches to left of left load, was noted. At 26,000 lb. diagonal crack marked (3) appeared. Maximum load 26,000 lb., diagonal tension failure.

Beam No. 222.5. At 16,000 lb. vertical crack was noted 6 inches to left of left load. At 20,000 lb. one 5 inches to left of centre and at 22,000 lb. 3 inches to right of centre. At 20,000 lb. diagonal cracks were noted 10 inches to left of left load and 3½ inches to right of right load. Failure occurred by diagonal tension. Maximum load 23,700 lb. All the concrete broke away from bottom of second stirrup to left of left load. Reduced section could be plainly seen. Stirrup did not slip.

Beam No. 223.1. At 16,000 lb. diagonal crack 3 inches high marked (1) was noted. At 18,000 lb. this crack was 5 inches high and diagonal crack 4 inches high marked (2) was noted. Crack marked (1) opened wider at maximum load of 19,000 lb. and extended almost to load point. Failure by diagonal tension at right end.

Beam No. 223.5. At 19,000 lb. diagonal cracks were observed 8 inches to left of left load and 8 inches to right of right load. At 22,000 lb. a diagonal crack was noted 14 inches to right of right load. Maximum load 22,600 lb.

Failure occurred by diagonal tension and failure crack was more nearly vertical than usual. Failure crack was limited to space between last three stirrups nearest the load. A loose stirrup was noted 6 inches to left of left load.

Beam No. 223.6. Diagonal cracks were noted 12 inches to left of left load and 9 inches to right of right load. Crack at right end extended almost to load point. Failure by diagonal tension at load of 21,000 lb.

Beam No. 224.5. At 14,000 lb. diagonal crack marked (1) was noted, at 15,000 lb. (2), at 16,000 lb. (3), and at 17,000 lb. crack (4). The cracks which started from the bottom of the stirrups headed for the centre point of next stirrup toward load. Failure occurred by diagonal tension along diagonal crack at left end and several stirrups slipped at this end.

Digitized by Google

Beam No. 225.5. At 18,000 lb. crack marked (1) appeared. Failure occurred by diagonal tension along crack marked (2). Second stirrup from right end bulged out and drew down. Maximum load 22,000 lb.

Beam No. 225.7. At 17,000 lb. vertical crack 4 inches high marked (1) was noted and at 20,000 lb. diagonal crack 4 inches high marked (2). At 26,900 lb., the maximum load, the crack marked (2) extended almost to load point. Load dropped to 16,000 lb. Failure occurred by diagonal tension. Concrete around second stirrup to right of right load was very lean. Lower part of the stirrup on each side was exposed and stirrup slipped a little.

Beam No. 226.5. At 18,000 lb. the vertical crack 5 inches high was noted at stirrup 7 inches to left of left load. At 19,000 lb. a diagonal crack 4 inches high was noted 15 inches to right of right load. At 20,000 lb. the cracks were enlarging and at maximum load of 20,100 lb. a diagonal crack 6 inches high was noted 8 inches to right of right load. Load dropped to 11,300 lb.

Beam No. 226.6. At 16,000 lb. diagonal crack 3 inches high marked (1) was noted, at 18,000 lb. vertical crack along stirrup 5 inches high marked (2) and at 19,000 lb. the cracks marked (3) and (4). At 20,000 lb. diagonal crack marked (5) appeared and other cracks were enlarging. At maximum load 21,000 lb., vertical crack marked (6) was noted; diagonal cracks were lengthening. Load dropped to 14,000 lb. and diagonal crack (1) was opening. Failure by diagonal tension at left end. The stirrups were quite close to sides of beam and were wrapped in paper for the lower 4 inches.

Beam No. 227.5. At 18,000 lb. small vertical cracks were noted 2 inches to right of right load, 4½ inches to left of left load, and at first stirrup 2 inches to left of left load on further side of beam. The latter crack was 4 inches long. Failure crack started at bottom of second stirrup 7 inches to right of right load, ran up stirrup 2½ inches, then to first stirrup at a point 3¼ inches from top, then upward along the stirrup. Maximum load 20,000 lb. Two stirrups were exposed at left end.

Beam No. 227.6. Cracks were noted on both sides of beam at 15,000 lb. No cracks noted at left end of beam. Failure was rather sudden and was due to diagonal tension. Third and fourth stirrups from right end were found to have slipped ⅛ or ¼ inch. The stirrups were not well embedded, especially at north end where failure occurred. Maximum load 16,400 lb.

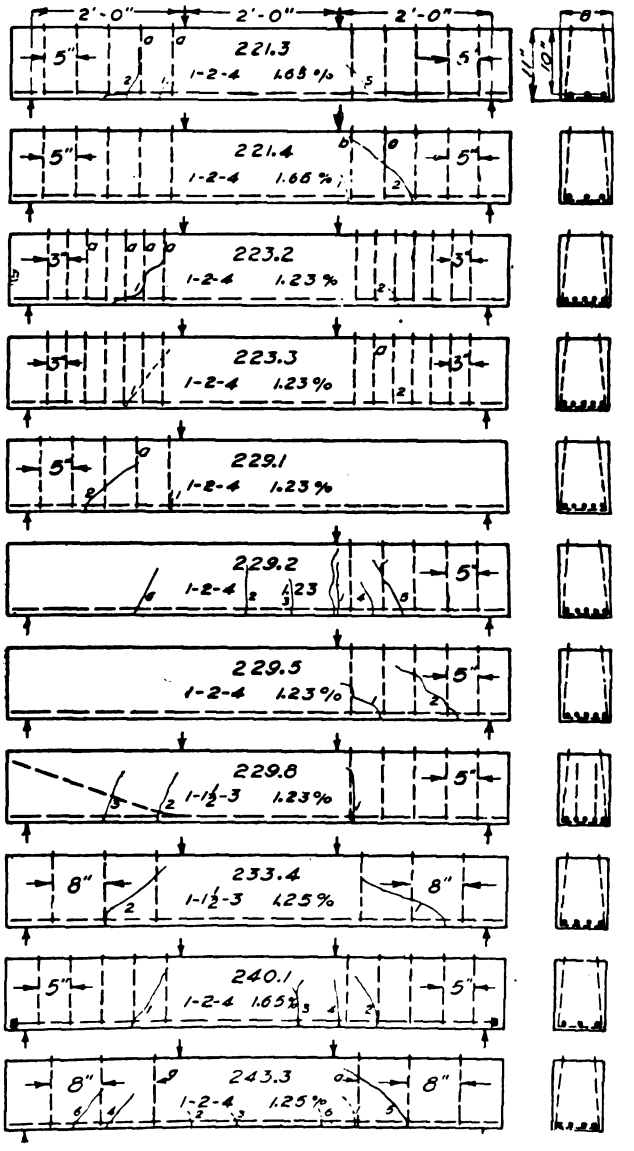
Beam No. 228.5. At 16,000 lb. a diagonal crack 5¼ inches high was noted 3 inches to left of left load. At maximum load, 17,500 lb., a diagonal crack 5½ inches high was noted 6 inches to right of right load. Failure occurred along the diagonal crack noted at 16,000 lb. The crack ended at bottom of beam at a point near first stirrup to left of load. First two stirrups at left end on further side of beam were showing at bottom. This fact did not affect the results, however.

Beam No. 228.6. At 19,000 lb. diagonal crack was noted 8 inches to right of right load on further side of beam and extended upward 4 inches. At 20,000 lb. diagonal crack was noted 12 inches to left of left load and extended toward load point, starting at fourth stirrup from left end. One stirrup showed slightly at right end. Maximum load 21,400 lb., failure occurring by diagonal tension.

Beam No. 221.3. At 24,000 lb. crack marked (1) noted, at 27,000 lb. cracks marked (2) and (3), each being about 3 inches high. At 29,000 lb. cracks were lengthening. At 31,000 lb. the two stirrups marked (a) slipped as crack (2) opened. After the maximum load of 31,100 lb. the load fell off to 18,400 lb., and failure crack gradually opened.

Beam No. 221.4. At 20,000 lb. crack marked (1) noted. At 21,000 lb. stirrup marked (a) slipped. At maximum load, 21,170 lb., stirrup marked (b) slipped. Load fell off and crack gradually widened. Diagonal tension failure.

Beam No. 223.2. At 22,000 lb. crack marked (1) noted. At 24,000 lb. this crack was 7 inches high and crack marked (2) was noted. Maximum load 24,600 lb. Gradual failure by diagonal tension. The load was taken off and then applied again. It rose to 13,300 lb. then fell off to 12,200 lb. as failure crack opened and stirrups marked (a) slipped.



Beam No. 223.3. At 20,000 lb. crack marked (1) noted and at 23,000 lb. this crack was 7¼ inches high. Maximum load 26,150 lb. Failure was gradual and stirrup marked (a) slipped after beam started to fail.

Beam No. 229.1. Loaded at one point. At 20,000 lb. crack marked (1) noted 3 inches high. At 22,000 lb. diagonal failure crack marked (2) opened and stirrup marked (a) showed signs of slipping. Load dropped to 17,000 lb.

Beam No. 229.2. Also loaded at one point. At 14,800 lb. vertical crack marked (1) noted. At 18,000 lb. cracks marked (2), (3) and (4) noted. At 20,000 lb. crack marked (5) appeared and other cracks lengthened. At 24,200 lb. crack under load was 8 inches long and ⅛ inch wide. Maximum load 25,400 lb., failure occurring by tension in steel. This shows a high resistance for the portion of the beam without stirrups.

Beam No. 229.5. Also loaded at one point. At 13,000 lb. crack marked (1) noted. At 13,400 lb., the maximum load, crack marked (1) was 4 inches high, and crack marked (2) was noted. Load fell off to 12,000 lb., failure occurring by diagonal tension. No signs of stirrups slipping and stirrups were not exposed.

Beam No. 229.8. Stirrups at one end only; at other end two bars bent up. At 14,000 lb. crack marked (1) was noted. At 20,000 lb. cracks marked (2) and (3) were noted, the former being 4 inches high and the latter 8 inches. Cracks (1), (2) and (3) increased in length regularly as load was applied, and at 26,000 lb. cracks (2) and (3) were about 9 inches long and crack (1) 11 inches. Crack (1) then widened appreciably. Maximum load 26,100 lb. Failure occurred at the end having stirrups and took place slowly.

Whether slip of stirrup along longitudinal bar or slip of the latter occurred is not known. Concrete was rich mixture.

Beam No. 233.4. At 18,000 lb. cracks marked (1) and (2) were noted. Up to maximum load of 26,300 lb. the cracks gradually lengthened and failure occurred by diagonal tension.

Beam No. 240.1. This beam had nuts and washers at ends of longitudinal rods. At 26,000 lb. cracks marked (1) and (2) appeared. At 33,000 lb. cracks marked (3) and (4) were noted and other cracks were lengthening. Failure occurred by tension in steel at 34,800 lb. followed by crushing of concrete. Stirrups did not slip.

Beam No. 243.3. At 20,000 lb. crack marked (1), 3 inches high, appeared. At 21,000 lb. crack marked (2) noted near

Digitized by Google

left load point. At 23,000 lb. crack marked (3), 3 inches high, appeared. At 26,000 lb. diagonal crack marked (4), 4½ inches high noted at left end of beam. Crack marked (1) was 7 inches high at this load. At 30,000 lb. crack marked (5) was noted. At 34,000 lb. cracks marked (6) and (7) were noted, the other cracks were lengthening and at this load stirrups marked (a) had slipped. Maximum load was 34,200 lb., failure occurring by diagonal tension.

LONDON MUNICIPAL HEAT SUPPLY.

By ALFRED E. WHEELER, C.E.

MUCH has been spoken and written in the past on the subject of Smoke Abatement, but it would appear that little practical good has resulted in spite of the deliberations of numerous Committees and Commissions which have sat to consider the question.

In a recent lecture on the subject the Vice-President of the Manchester Chemical Club stated that the first step to the solution of the smoke problem must come by attacking the domestic coal fire. Authorities have agreed that 70 per cent. of the smoke in the atmosphere proceeds from domestic chimneys, and no engineer of experience will see any reason to suspect exaggeration in this statement, since he knows very well that the construction of the old open grate is opposed to the conditions necessary to smokeless coal combustion.

Without entering into a long dissertation on the chemistry of the combustion of coal, the reason of the failure of most domestic fire grates may be made apparent in a few words. Combustion is the "combining" of the oxygen in the air with the carbon and hydrogen present in the coal producing a chemical change, which, like all other chemical changes, evolves heat in the process, but a necessary condition of perfect combustion provides that the air should pass *through* the hot fuel and not *over* it. There are comparatively few domestic fire grates which fulfil this condition, hence the trouble which it is sought to remedy. It is, however, a comparatively simple matter to burn coal smokelessly under carefully studied conditions of firing and draught in specially constructed furnaces, and even low grade fuel may be used to great advantage.

The smoky condition of the domestic grate is not more remarkable than its supreme wastefulness of heat. In some tests carried out for the Smoke Abatement Committee, Mr. D. K. Clark found that no less than 58 per cent. of the total heat of coal was lost by this imperfect combustion, and this again will be easily understood by architects who have experienced the loss of efficiency in boilers occasioned by leaky flues; hence it would appear that each household is wasting more than half the money spent upon its coal to the detriment of everyone and the good of nobody, and the moral is read each time an excess of atmospheric moisture carries these unconsumed products in suspension and gives us a real sample of City fog.

Sufficient has been said to show that the most effective solution of the problem would be to prohibit the use of domestic coal fires altogether, but what authority will be bold enough to take this step? Granted that coal may be burnt both smokelessly and, at the same time, more economically on a large scale, the problem of the distribution of the heat remains, and to carry out a scheme of heat distribution for London would necessarily be an undertaking of so gigantic a nature as to border on the impossible. The latter word, however, is generally an insignificant one in the vocabulary of the modern engineer, who is happily not appalled by magnitude. Our large gas, water, and electricity undertakings, although marvels of magnitude, have grown to their present proportions gradually, hence their conception strikes no one as remarkable; therefore with a due appreciation of the stupendous nature of the scheme. I propose to suggest, by means of a few figures, a method for carrying into effect a public heat supply for London, and thus make an effort to strike an effective blow at the smoke trouble.

The idea of central station heat generation for public supply is, of course, not new. Prof. J. D. Hoffman read a very interesting paper before the American Society of Heating and Ventilating Engineers at Chicago in 1905, in the course of which a plant of this nature was described, and the ensuing discussion also disclosed various other systems established for the purpose of supplying heat on a public supply basis. None of these systems, I must submit, or indeed any system which I have yet been able to trace, has quite fulfilled the object which forms the subject of this article, *i.e.*, the distribution of *heat* distinct from heat associated with water or its vaporised condition, steam. Either of these forms introduces complications involving in the one case working charges due to the formation of chemical deposit in the mains, and in either case a considerable outlay for water.

One of the members of the American Society in the debate already referred to stated that he proposed taking the attitude of believing that heat will be successfully and cheaply distributed by wire as power and light are now, and that he deemed it wise to "go slow" on pipe systems, and do as much heating as possible by wire. I propose to take more than mere passing notice of this opinion, because it would seem surprising that it should be seriously entertained by a responsible heating engineer. Heating by means of electric radiators, although doubtless having a very attractive sound, has been found to cost rather more than fourteen times that of heating by steam or hot water (Prof. R. C. Carpenter in the latest edition of his work on heating buildings quotes even a higher figure than this), yet its facilities for regulating the heat given off are not comparable with those available by the latter methods. A brief comparison of figures may assist in demonstrating this point. The equivalent of an electrical Board of Trade unit is 3,440 British thermal units, and this quantity of electricity at the cheapest rate it is at present retailed at costs one penny. Coke such as is commonly burned in a low pressure steam or hot water heating boiler at, say, 20*s.* a ton, has an average calorific value of 13,000 B.T.U. per lb. A large proportion of this heat, however, never finds its way into the heating medium at all, and at a very conservative estimate not more than 8,000 B.T.U. per lb. are utilised. A large experience of heating apparatus shows that an average of 33⅓ per cent. is radiated from supply mains and pipes, therefore the total heat available for actual heating becomes about 5,333 B.T.U. per lb., and costs 0.107*d.* This, it will be seen, is considerably more than the heat value of an electrical Board of Trade unit, the equivalent cost of heat by coke in an ordinary way running out at 0.069*d.*, or rather less than *one-fourteenth* that of electricity.

A comparison of the cost of electric heating with heating by steam taken from a steam boiler puts the relative costs at

Electricity	3,440 B.T.U.	=	1*d.*
Steam	3,440 do.	=	0.061*d.*

The latter cost, deducting the allowance—of 33⅓ per cent. as before—for the radiation from the pipes shows electricity for heating to be 16.3 times more costly than a steam-heated system. In fairness, however, it should be pointed out that some part of the general working costs of the steam plant should be debited to the account of the heating apparatus, although, on the other hand, the cost of 1*d.* for the electrical equivalent of 3,440 B.T.U. on the electrical side includes nothing for upkeep of lamps, rent of meter, &c.

Neither is it surprising that there should exist so great a disparity between the relative costs of heating by electric means and by direct application of heat, if we consider the multifarious stages by which the former is accomplished as compared with the latter.

All the electric corporations or companies in London generate their electric power by means of steam engines. Indeed, such a method is almost universal with a few notable exceptions, in this country at any rate. True, in some parts of America, especially at Niagara, on the Continent, and even in our own country, there exist supplies of natural water power, which have been turned to good account for the purpose of generating electrical energy, but the great bulk of the power used in the generation of electric current is obtained from heat engines, and it is in respect of these latter that these remarks are particularly addressed. Let us then for a moment review the stages through which heat must pass on its electrical progress to the consumer by way of the steam engine.

Assuming as a representative case that the dynamo is direct coupled to a very efficient high speed compound condensing engine, consuming 15 lb. of steam per i.h.p. per hour, at an initial pressure of 120 lb. per square inch. The coal is fed into the boiler furnaces to generate the steam, which in turn passes from the boiler to the cylinders of the engine to do its work of transmitting the heat supply. The heat account per h.p. up to the point when it reaches the dynamo is as follows:—

Heat value of coal fed to boilers	21,750	B.T.U.
Do. work at dynamo ...	2,545	do.
Total loss per cent....	88.5	

Digitized by Google

Allowing that the dynamo gives off from its terminals as much as 95 per cent. of the power supplied to it, the heat value given off will be nearly equal to 1,584 B.T.U. per 1 lb. of coal. The further loss accruing in transmission we will ignore. Thus the heating value of the 14,500 B.T.U. per lb. of coal has, by the time it has reached the consumer, dwindled to 1,584 B.T.U. *or equal to a loss of 89.08 per cent.*

As we have already seen when coke is used as fuel in a direct heating apparatus, the net heat utilised per lb. for heating purposes is about 5,333 B.T.U., therefore if we find that by the electrical-cum-steam-engine method we are only able to utilise 1,584 B.T.U. per lb. of coal, the natural inference is, that in order to transmit the same heat electrically as by the direct method, we must do so at the extraordinary expenditure of about 236 per cent. *more* fuel! Nor may we anticipate a much greater efficiency in the steam engine of the future, any further developments in the direction of economy being improbable. There may possibly be some hope in the steam turbine, but a recent test of a modern type of Curtis turbo-generator, with a steam pressure of 153 lb. per sq. inch and working with a vacuum of 27 inches, showed a resulting thermal efficiency of only 14 per cent.

Although the heat engine works with such prodigality of heat, it is nevertheless practically the universal prime mover employed in the work of generating electric energy on anything approaching an extensive scale, therefore if electricity is to be the medium for distributing heat in the future to London the heat engine must necessarily be the means employed for generating the current. It is thus patent that in adopting the principle of electrical distribution we are pledging ourselves to a waste of money, and what is more important—that which money cannot replace—viz., our stores of coal.

There is another form of heat engine, however, which merits more than a mere casual mention, and I need hardly say I refer to the various forms of internal combustion engine, in which the heat for obtaining the power is produced within the engine itself by gas or oil.

One of the highest forms of this type of heat engine is the Diesel principle of internal combustion, in which oil is injected into highly compressed air in the cylinder, the heat due to compression igniting the charge; but perfect though this application is, the thermal efficiency of the Diesel engine is but 40 per cent. at the fly wheel of the engine, and (allowing the same efficiency for the dynamo as before) only 38 per cent. at the terminals of the generator.

It may be thought that I have gone into detail somewhat unnecessarily in the matter of the heat engine, but I have done so for two reasons—first, to correct once for all the erroneous impression that electricity may be made to play a profitable part in any scheme of heat distribution on a large scale, however efficient an agent it may be for the transmission of power or for lighting. A system which requires the expenditure of from 50 to 250 per cent. more fuel to do a given duty is the system which must be avoided unless it is desired to run the finances of London on the most approved lines of harebrained philanthropy.

Secondly.—In any scheme which we may formulate for the prevention of smoke we are bound to consider the claims of the extensive user of power. It would be a burdensome and unjust imposition to compel the manufacturer to demolish his steam plant—which may be in excellent condition—in pursuance of a policy of prohibition of the smoke-producing use of coal unless he can be shown some alternative, and not necessarily more costly, source of power to take its place.

An efficient type of industrial steam-engine may be constructed to run on 25 lb. of steam per i.h.p. hour, with a thermal efficiency of 5.28 per cent., and an expenditure of coal per i.h.p. of 3.34 lb. If it is pointed out to the owner of this coal-eating monster that a suction gas plant will run on an expenditure of 0.8 lb. of coal per i.h.p. hour, and *save 75 per cent. of his coal bill*, he would doubtless cheerfully scrap his steam plant, if only in the interests of his own pocket. The alteration is also more advantageous to him than is at first apparent, as it obviates the necessity of all feed pumps and such like incidental plant, lowers considerably his water bill, and reduces skilled oversight to a minimum. To some, on the other hand, the facilities offered by the local electricity supply companies may appeal.

We have thus far progressed in two directions:—

(*a*) We have seen how NOT to supply heat to London.

(*b*) We have supplied the method of replacing the existing smoky and wasteful steam plants with the smokeless and economical gas plant.

Before proceeding to a more or less detailed description of the method which will be suggested for the supply of heat to London, I would like to emphasise a point already referred to, and which does not seem to have been aimed at in similar attempts which have been made in various parts of the world. Any scheme designed to supply heat should do so as distinct from water or any other medium. It was pointed out in an earlier passage that if a supply of water accompanies the supplies of heat complications are introduced, not the least of which being a large water bill incurred at the generating station, and doubtless past failures might largely be traced to this cause, making as it does directly against economy in working. Among other contributory causes, which will be discussed later in their proper places, are the following:—

1. First cost of water a continual charge.
2. Heating each fresh supply of water from its initial temperature.
3. Extra working cost due to chemical deposit in mains and boilers.

From these points it will be gathered that an efficient scheme should embody the following requirements:—

1. No cost for anything above and beyond the actual heat.
2. To commence with a stock-in-trade of heat (as it were), and merely replace heat sold and that lost by depreciation.
3. Keep all mains and boilers free from chemical deposit, so that a heavy working charge may be avoided.

It must also be remembered, in connection with the last-named reservation, that any system which involves the periodical cleaning or replacement of mains in London streets is foredoomed to failure. It should also be noted that scale formation inside boiler plates or tubes results in a serious loss of heat efficiency, however thin the deposit.

(To be continued.)

YORK BEFORE THE CONQUEST.

A LECTURE entitled "The Earlier Forms and Reminiscences of York Minster" was delivered recently before the Yorkshire Philosophical Society by Mr. G. Benson, A.R.I.B.A. He commenced his lecture by saying that a wedding introduced the Church into York. Edwin, King of Pagan Northumbria, which stretched from the Forth to the Humber, had extended his rule to the channel by compelling the other Anglo-Saxon kings to acknowledge him as their over-lord. King Edwin in the year 625 married the Christian Ethelberga, sister to the King of Kent. The Queen brought to York her chaplain, Bishop Paulinus. Efforts were made to induce the King to embrace Christianity. Pope Boniface sent him a letter and presents. Subsequently King Edwin summoned his Witan before the idol temple at Goodmanham to discuss the new religion. The King, the council and the pagan high priest were converted by Paulinus. Out of the fire which consumed the idol temple at Goodmanham arose, phœnix-like, the minster at York. The King came to York to his palace, the old Praetorium, within the Roman fortress. In the adjoining wide main street which lay from north-east to south-west, the King built a church. The King selected York as the archiepiscopal see and induced Pope Honorius to bestow the pallium on Paulinus. York, besides being the political capital, now became an ecclesiastical capital or metropolis. The minster became the metropolitan church of the Province and the bishop the metropolitan. So that York was both capital and metropolis at once, a dignity to which London never attained, for it has always in Church matters been subject to the See of Canterbury. A conjectural view of the stone minster of King Edwin was shown on the screen. It was seen standing amidst the ruins of the old Roman fortress. The Roman walls, tower and gateway, and some of the buildings in the interior of the camp were depicted.

In York Museum is a jewelled silver cup decorated with birds, animals, and interlaced patterns. Some authorities consider it may have been made by one of the artificers from Rome, brought over by Wilfrid. If so, Mr. Benson suggested it might have adorned the altar at York Minster until looted by the Danes, who carried it over Stainmoor to Ormside, from whence it has been restored to York. After speaking of the events which led to the deposition and restoration of Wilfrid, Mr. Benson said many of the nobles sent their sons to be brought up in his household. This was the

Digitized by Google

beginning of St. Peter's School, of course not on the present site. Roger of Howden records that on Sunday, April 23, 741, a monastery in York was burnt. Moreover the A.S. Chronicle states this year (741) York was burnt. This fire appears to have destroyed the minster monuments, for there was an absence of such fine crosses of the period as are to be seen in part at Northallerton and Easby. The minster was restored. Archbishop Egbert, accompanied by Alcuin, a youth of twenty, and a scholar in the York school, in 755 travelled through France and Italy, and after a short stay in Rome returned to York, bringing many manuscripts to add to the library. Egbert was succeeded as Archbishop by the schoolmaster, Albert. Alcuin then became master of the school, which was carried on with great zeal. The library was the most famous in Europe. After an episcopate of ten years or so Bishop Albert considered a new cathedral was necessary. It was designed by Eanbald, who was assisted by Alcuin. The plan was similar to that of the churches of Rome. The axis of the old minster appears to have been north-east to south-west, and parallel to the streets in the Roman fortress; that of the new edifice was changed to east and west. The concrete foundation of the latter was revealed in 1829, and a plan made of it by John Browne. The new minster appears to have consisted of a nave 87 feet long and 23 feet 4 inches wide, with aisles and a tower chancel, and having porch chapels or transepts on either side. At the west end was a roofed-in narthex or porch. Alcuin described it as supported by solid columns under curved arches. It had a great number of apartments with separate roofs, and it contained thirty altars. The new minster was consecrated in October 780, to the Alma Sophia by the Archbishop ten days before his death. In the course of further remarks Mr. Benson said it was possible that some day or other York might come to appreciate Alcuin sufficiently to erect near the minster a cross of the Northumbrian type to the lasting memory of this illustrious schoolmaster even as Whitby had done for Caedmon. During the Norman invasion the city was fired and the minster destroyed. The whole of the buildings he had been describing have vanished except Roger's choir, and given place to the present magnificent structure.

THE PRESERVATION OF IRON AND STEEL.*

Introduction.

IT is significant of the present age that the tendency of thought amongst all nations is toward the conservation of natural resources. Increasing consumption of the world's supplies and constant decay of materials menace the future of the human race. It is evident that carbon, from which we derive energy, and iron, which provides the principal means of applying energy, are the materials which should particularly engage the attention of those who are studying the problems of conservation. The annual production of pig iron in the United States alone grew from 13,789,242 tons in 1900 to 25,307,191 tons in 1906; and while for the year 1908, owing to industrial conditions, it decreased to about 16,000,000 tons, it seems sure to again show an increase in the near future. How much of this enormous and constantly increasing world's production of iron and steel is wasted for lack of adequate preservation? Where will the growth of demand stop, and how many years will the world's ore supply stand the drain upon it? These are questions of vast importance, the answers to which can only be vaguely guessed. One thing seems certain: civilisation must learn to conserve more efficiently its stores of iron and steel already manufactured, and seek methods to prevent the almost resistless tendency of iron to return to its lethargic union with oxygen, from which it was won only by the consumption of vast quantities of the ever dwindling coal supply. It is not generally realised that about four tons of coal, or its equivalent, is used in preparing one ton of finished steel from the ore. The world's store of gold is not subject to loss by corrosion, but suffers to some extent from attrition, owing to the softness of the metal. If steel could by any means whatsoever be ennobled, and thus protected from the inevitable decay due to corrosion, future conditions for all possible years to come could be viewed with complacency. It is said † that there exists at Delhi an iron monument that, since the dim beginning of history, has been exposed to the weather without rust or decay, and yet this column has been provided with no protective coating other than that which the atmosphere has itself formed upon it. Could we to-day, with all our boasted knowledge and our great pneumatic processes, build its like? It is probable that we could not, and yet an art is not necessarily lost for ever. It is simply a question of whether or not it is worth our while to rediscover it.

The Corrosion of Iron.

It is the object of this paper to examine into the controlling factors that influence the causes and the cure of the corrosion of iron, and to inquire into the possible practical bearing of the results of recent research.

The author has in previous investigations *referred to the fact that the problem of the preservation of iron has three distinct phases. The first phase is concerned with the manufacture of a metal highly resistant to corrosion, such as is represented by the iron column of Delhi, or the splendid examples of hand-forged metal that have come down to us from past centuries, with which may be contrasted the pitted, lace-like condition of specimens of modern steel after only a few years' exposure to the atmosphere. The second phase concerns the general subject of protective coatings, which may consist of other metals, such as zinc, tin, copper, and lead, or of oil paints, varnishes, lacquers, and bituminous materials, or, finally, the production of a higher oxide on the surface, as in the Bower-Barf, Wells and Speller processes. The third phase includes the interesting study of the passive condition which iron is capable of assuming, and the possibility of maintaining the surface in such an ennobled condition.

Many discussions† have arisen in regard to the several rival theories of corrosion, but the evidence which has been collected in numerous recent researches appears to the author to prove beyond all argument that the corrosion of iron, like that of other metals, is an electro-chemical phenomenon.

In considering the corrosion of iron it is important to remember that, with possibly one or two exceptions, there are no elements that do not either dissolve in or combine readily with iron. It is also unique in the fact that the presence of very small quantities of impurities suffice to change its physical characteristics entirely. On account of this fact metallurgists scrutinise the hundredth of a per cent. of some of the principal impurities that are generally associated with this metal. This is particularly true, for instance, of the element phosphorus. It is so important to modern metallurgy that the amount of phosphorus should be controlled in certain forms of steel, that an animated discussion is going on at the present time between certain interests as to the maximum amount of phosphorus that a steel shall be allowed to contain, and the question at issue amounts to no more than a few hundredths of 1 per cent.

Manganese also is an element which is nearly always associated in modern metallurgy with iron and steel. Manganese decreases the electrical conductivity of iron, and as the percentage of manganese, starting from zero, rises, the electrical resistance increases up to a certain specific maximum. It will be seen that if the presence of manganese in iron raises the electrical resistance, any variation in the distribution of the manganese means that there will not be a constant electrical conductivity throughout its mass, or on any given surface. There is abundant evidence to show that manganese associates itself to a considerable extent with sulphur when both these impurities are present in steel.‡ That manganese sulphide shows a difference of electrical potential against steel is also well known. One who is familiar with the methods of modern metallurgy knows that the manganese is added for certain specific purposes, not as a rule quantitatively, but in accordance with the views of the ironmaster who has control of the mill or furnace. Moreover, the manganese is usually added by throwing lumps of ferro-manganese into the molten metal, either in the furnace itself, or in the ladle into which it

Digitized by Google

has been poured. Chemists know the extreme care that has to be taken in order to get uniform mixtures of substances in the course of chemical operations. In the large scale in which metallurgical processes are carried on, even if it were possible to take great care in the mixing, it still happens that when iron is cooled from the molten state segregation takes place; that is to say, the impurities, although they may have been thoroughly mixed in the molten mass, do not remain homogeneously distributed after the metal is cooled.

For these reasons we must remember that in studying iron and steel from the standpoint of their stability, under the conditions of service, we are not dealing with homogeneous pure metal. It is not difficult for an electro-chemist to believe that when such material is immersed in, or even brought into contact with, an electrolyte, electrolysis will take place upon the surface and thereby induce rapid corrosion. It is probable that the corrosion of all metals is more or less due to electro-chemical action. Before metals can be attacked at ordinary temperatures in the presence of water they must first pass into solution, and in passing into solution become ionised. This is true of copper, zinc, lead and other metals that suffer corrosion.

In accordance with the conceptions of Nernst * and the modern theory of solutions, all metals have a certain solution pressure which will operate until counterbalanced by the osmotic pressure. Iron, however, appears to differ from the other metals in one important respect. The corrosion of iron does not take place evenly and uniformly over the surface. On the contrary, it is a matter of common observation that iron corrodes rapidly at certain weak points, the effect produced being known as pitting. That this effect is produced by local electrolysis would hardly be doubted, even if it were not possible to demonstrate it by the use of the ferroxyl indicator.

Early in his investigations the author † observed that whenever certain specimens of iron or steel are immersed in water or in a dilute neutral solution of an electrolyte to which a sufficient quantity of phenolphthalein indicator has been added, a pink colour is developed. If the solution is allowed to stand perfectly quiet, it will be noticed that the pink colour is confined to certain spots or nodes on the surface. The pink colour of the indicator is a proof of the presence of hydroxyl ions, and thus indicates the negative poles. It may be added that some specimens of steel exhibit this phenomena much more quickly and distinctly than others.

Since phenolphthalein shows only the nodes where solution of iron and subsequent oxidation does not take place, Walker ‡ suggested the addition of a trace of potassium ferricyanide to the reacting solution, in order to furnish an indicator for the ferrous ions whose appearance marks the positive poles. If iron goes into solution, ferrous ions must appear, which, with ferricyanide, form the well-known Turnbull's blue compound. If the reagent is stiffened with gelatin or agar-agar, diffusion is prevented and the effects produced are preserved. For this combined reagent, which indicates at one and the same time the appearance of hydroxyl and ferrous ions at opposite poles, the author has suggested for the sake of brevity the name "ferroxyl." If the reagent has been properly prepared the colour effects are strong and beautiful. In the course of a few days the maximum degree of beauty in the colours is obtained, after which a gradual deterioration sets in.

In the pink zones, as would naturally be expected, the iron remains quite bright as long as the pink colour persists. In the blue zones the iron passes into solution and continually oxidises, with a resulting formation of rust. Even the purest iron develops the nodes in the ferroxyl indicator, but impure and badly segregated metal develops the colours with greater rapidity and with bolder outlines. This result would of course be expected, as in pure iron the formation of poles would be conditioned by a much more delicate equilibrium than in impure iron, where variations in concentration of the dissolved impurities would stimulate the electrolytic effects.

The ferroxyl mounts are prepared as follows:—A 1½ per cent. solution of agar-agar is first made by dissolving a weighed quantity of powdered agar in the requisite amount of water. This solution is boiled for one hour, fresh water being added to replace that lost by evaporation. It is then filtered while hot, and 2 cubic centimetres of standard phenolphthalein indicator added to every 100 cubic centimetres solution, after which it is brought to a perfectly neutral condition by titration with a tenth normal solution of potassium hydroxide (KOH) or hydrochloric acid (HCl), as the case may be. The addition of 7 cubic centimetres of a 1 per cent. solution of potassium ferricyanide to every 100 cubic centimetres of solution is then made, and the ferroxyl reagent while still hot is ready to use. Enough of the reagent should be poured into a Petri dish just to cover the bottom and the dish floated in cold water until the agar has jellied. A clean sample of iron is then placed on this bed of jelly and covered with the hot solution. After the final addition of agar the dish should not be moved until thoroughly cool. While the colours sometimes show up immediately, they usually require from twelve to twenty-four hours to attain their most perfect development. The mounts may be preserved for many months by keeping the surface of the agar covered with alcohol.

In the author's opinion these effects which are produced in the ferroxyl indicator constitute a visible demonstration of electrolytic action taking place on the surface of iron and causing rapid corrosion at the positive nodes. This electrolytic action, which is shown to take place whenever iron rusts, should not, however, be confused with the rapid destruction of steel in the neighbourhood of vagabond currents from high potential circuits used for electric lighting or tramways. In order to avoid such confusion of terms and ideas, it has been proposed to speak of the underlying electro-chemical cause of corrosion as autogenous * electrolysis, or more briefly, auto-electrolysis.† It is not the author's intention at present to collect all the evidence which tends to prove that auto-electrolysis always takes place when iron rusts; this has already been done in numerous papers by several independent investigators.‡ The case may be allowed to rest on the evidence of the ferroxyl test, which at least is conclusive as to the fact that iron is going into solution and oxidising more rapidly at certain points than at others.

NOTES ON BOOKS.

"Greek Architecture." By Edith A. Browne. (London: Adam & Charles Black. *3s. 6d.* net.)

To concentrate the history and explanation of Greek architecture into the small compass of thirty-six pages of square demy octavo, in large type, so that a reader, knowing "nothing whatever about Greek architecture" and whose "knowledge of classical history is what an earnest student would dub elementary," may in a short hour or two be enlightened as to the sources from which Greek architecture sprung, the causes that actuated its development and the merit of the achievement it attained, is a remarkable performance, and we congratulate the authoress of this little volume on the perspicacity with which she has selected the essential and the lucidity with which she has expounded the material elements of Greek architecture. The Philistine who reads this book can scarcely fail to understand it, and, having understood, will be possessed of such a true comprehension of the salient features of Greek architecture that he will not need further instruction until he leaves the ranks of amateurs and joins that of the professional or earnest students. Commencing with an account of "The First Builders in Europe," the titles of Pelasgic, Primitive and Prehistoric are dismissed as misleading, and the positions of the Mycenæan, Ægean and Minoan civilisations in the history of ancient art are explained briefly but clearly. Then we have the character and methods of "the Greek builders" and the nature and form of "Greek buildings" concisely and yet adequately described, followed by a chapter on "Greek Means to Beautiful Ends," in which the root principles of Greek architecture are logically formulated and from which the amateur will learn that its excellences are founded on situation, proportion, form, line, ornament, sculpture and colour. A final chapter explains "The Influence of Greek Architecture," and having completed this the reader will understand the inwardness of Greek building and comprehend the "great artistic debt owing to the Greeks by the world in general and the European builders in particular." Not the least valuable part of the book is the series of forty-eight full-page illustrations from good photographs of Greek buildings as they appear to-day.

"Steel Construction." The *Illustrated Carpenter and Builder* Technical Manuals. (London: John Dicks Press, Ltd. 6*d*. net.)

This manual is described as "an easy introduction to the science of designing and building in steel." Though it is offered to the student of constructional engineering as an introductory text book, it is suggested that many architects and builders in general practice will probably find that the work will meet all their requirements. This seems rather a reflection on the profession. It is, however, safe to say that anyone who masters this primer will be better qualified to deal with this form of construction than some architects who make an extensive use of steel. The chapters are clearly written, and as far as possible exclusively treat of one feature at a time; beams, columns, connections, roofs, grillages, floors, bracing and staircases, steel cage work and ferro concrete have each their separate chapters. The novice may be puzzled by the misprint on p. 15, where we are told that "beams" are usually subjected to what is termed *beading*" —instead of "bending." The subject is a difficult one, and no doubt it has been reduced to a surprising degree of simplicity; the book, however, has not yet made it quite so simple as the A B C.

"Reinforced Concrete Construction." (London: *The Local Government Officer*. 1*s*.) "Simplified Methods of Calculating Reinforced Concrete Beams." (London: Whittaker & Co. 6*d*.)

The above are two booklets in which Mr. W. Noble Twelvetrees deals with a subject of which he has long made a study. The first is based on articles which he recently supplied to the *Local Government Officer*, and is divided into four chapters. Chapter I. explains the theory of beams and columns, Chapters II. and III. give formulæ for each, and Chapter IV. deals with practical construction. Mr. Twelvetrees in his second pamphlet offers "a standard system of notation capable of meeting all requirements and harmonious with the notation employed more or less consistently by writers on construction." Under the existing conditions something like chaos exists, and anything that can be done to make order out of it must be welcome. The system should be considered by some of the engineering societies.

OUR CONTEMPORARIES FROM OVER-SEAS.

THE *American Architect* illustrates the Carnegie Library Building of the Georgia School of Technology, Atlanta, by Messrs. Morgan & Dillon; the College Building of the Atlanta College of Physicians and Surgeons, by the same architects; and the First Presbyterian Church at Chattanooga, for which Messrs. Bearden & Forman and Messrs. McKim, Mead & White are associated as architects.

The *Berliner Architekturwelt* occupies itself with some of the civic buildings of Rixdorf, which town has grown to a population of about 217,000 from the 90,000 that it contained in the year 1900. A Rathhaus on a large scale has been projected and partly erected, from the designs of Reinhold Kiehl, and two of the municipal schools are also illustrated. Herr Reinhold Kiehl is the architect of these also.

The *Engineering Record* (New York) completes the description of the central heating and lighting plant at the United States Military Academy, commenced in previous issues.

Correspondence

[The Editor will not be responsible for the opinions expressed by Correspondents.]

The Institute and Registration.

SIR,—My reason for having given notice to bring forward two resolutions at the general meeting on June 7 is to correct what appears to me to be a wrong impression which has been conveyed to the members of the Institute in the circular letter signed by the president, the four vice-presidents, and the hon. secretary, and posted to every member of the Institute in the envelope with the voting papers.

As a member of the Institute who has followed the registration movement for some years, I am anxious to see its fulfilment in due course. At two general meetings at the Institute, one held on April 3, 1906, the approval of an application to Parliament for a Bill was unanimously agreed. It was then felt that contentious matter should be dropped, as, unless the profession could approach Parliament with practical unanimity, there was little chance of getting the Bill passed. So contentious matters were dropped, and the committee recommended in their report that "the Institute should confine itself to attempting to obtain Parliamentary recognition for its membership, an attempt which it was believed would meet with very general support." That belief on the part of the committee was well founded, for their report was unanimously adopted at a general meeting, when it was "resolved, after a revised or supplemental charter had been obtained, that the Council should prepare and present a Bill to Parliament."

This view was held unanimously on April 3, 1906, and was adopted at a subsequent general meeting held at the Institute on March 4, 1907, as follows:—

"The Council have given careful consideration to all the principles above enumerated, and recommend that as a first step a revised or supplemental charter should be applied for, embodying as many of the principles set forth in Section 11 as possible, *and that when this has been done an Act of Parliament should be applied for as soon as practicable.*"

The circular says:—

"As soon as all architects are thus practically united within the Institute, an opportunity will be afforded of considering the possibility of submitting a Bill to Parliament."

To my mind, after the definite and unanimous expression of opinions at general meetings, the wording of the circular conveys an unauthorised change of policy.

Now, to prevent any misunderstanding occasioned by the circular letter, I am bringing forward the following resolution:—

"That in the opinion of this meeting the circular letter enclosed in the envelope accompanying the voting papers for election of candidates to the Council and standing committees does not correctly represent the policy of the members of the Institute as embodied in an adopted report at a general meeting held at the Institute on March 4, 1907."

My second resolution is:—

"That this meeting desires that in future no circular letter be posted in the envelope containing the ballot papers which has not first received the approval of the Council."

I feel that this resolution requires no argument to commend itself. I would, in fact, prefer having the resolution simply put to the meeting without comments. I fear if this form of circularising the members is taken as a precedent an objectionable custom would become established.

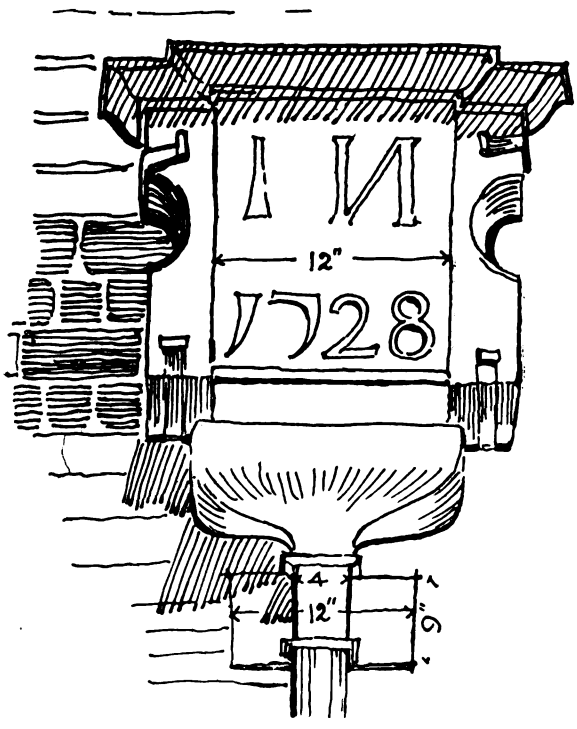
Believe me, yours faithfully,

GEORGE HUBBARD.

May 27, 1909.

GENERAL.

West Stanley Council, Durham, have awarded the premiums of 30*l*., 20*l*. and 10*l*. offered for three best plans of new Council offices to the following architects out of sixty-six who competed:—1st, Mr. J. W. Wilson, Sutton Coldfield, Warwickshire; 2nd, Mr. John J. Eltringham, Blackhill; 3rd, Mr. Edwin Bowman, Westgate Road, Newcastle; reserve, Charles Edeson, Scarborough. The estimated cost of the building is 3,000*l*.



The Council of the Royal Institute of Architects of Ireland held a special meeting at 31 South Frederick Street, Dublin, last week. Mr. F. Batchelor occupied the chair. The President stated that the National University had decided to provide a school of architecture in the University, together with a lectureship carrying a salary of 200*l*. per annum. The report of the professional practice committee was read and adopted. Mr. Batchelor stated that it would be necessary for a representative of the Institute to go to London and interview the officials of the Board of Trade with reference to the Articles of Association. The President was appointed to attend.

At a Meeting of the Canterbury education committee on Tuesday the Surveyor brought up amended plans for the school of art. By curtailing the basement accommodation he had reduced the estimated cost by 800*l*., which would bring the amount of the lowest tender down to 2,400*l*., exclusive of furniture. The plans were referred to committee.

At a Special General Meeting of the Incorporated Association of Municipal and County Engineers, at Malvern, last Saturday, under the presidency of Mr. E. Purnell Hooley (county surveyor of Nottinghamshire), it was resolved, with two dissentients, to change the name of the Association to the "Institution of County and Municipal Engineers."

RAIN-WATER HEAD AT COMPTON WYNYATES.
From a Sketch by BANISTER FLETCHER.

THE WEEK.

LOYALTY and affection for the present occupant of the Presidential chair saved the vote of censure at the Royal Institute last Monday night, and Sir ASTON WEBB rightly gauged the feeling of the members generally in the line that he took by appealing to their consideration for the personality of Mr. ERNEST GEORGE, of whom it was very generally expressed—in the lobby—that "he is a dear old boy, *but* a very poor chairman." It was widely felt, although Mr. HUBBARD's motion was defeated by a small majority, that the circular issued with the voting papers was a mistake, and it was also very generally believed that Mr. GEORGE had no hand in its initiation or its composition. Hence the sufficiency of the majority was due to the kindly feeling of those who at all costs were willing to help the President out of the mess.

IT would have been far otherwise if all the speeches by supporters of the signatories of the circular had been in the tone of that by Mr. BURNET. There will be grievous trouble in the Royal Institute if the position is maintained that the Council, when elected for the year, are the autocrats of the Institute, and may disregard or flout the wishes and resolutions of the members as expressed in general meetings. The members of the Council are the representatives and executive of the general body, not its pastors and masters. Granted that they have managed their own business so successfully as to become the most prominent men in the profession, it is not likely that the thousands of architects of whom they are the representatives will tamely acquiesce in the business of the Royal Institute being managed by the elect, regardless of the opinions, the knowledge and the experience of their constituents.

THERE is not much probability of the mistake being repeated if one may judge from the amusing eagerness with which the supporters of the signatories jumped at a suggestion by Mr. MIDDLETON that a by-law should be drafted forbidding such a thing in future, and promptly adopted it as an amendment to Mr. HUBBARD's second resolution. When Mr. HUBBARD's propositions were disposed of, nobody seemed to want the answers to Mr. CROSS's questions, which as a matter of procedure ought to have been put and answered first. If they could have been answered satisfactorily there would have been less disposition to discuss Mr. HUBBARD's resolutions, and these would have been negatived in very quick time. Then the meeting might have found an opportunity to proceed with the by-laws, which are now hung up till next Monday.

HOLBEIN's *Duchess of Milan* has been saved for the nation, and the picture will remain at the National Gallery—and the dealers will pocket their profit. Which only shows that if you scream loud enough you can find money in England ready to be contributed to any sentimental object. The Dean and Chapter of Winchester are still some thousands short of the 100,000*l.* that Mr. JACKSON says is needed to make it safe. We have no sympathy with the Dean and Chapter. They do not scream loud enough. But we should like to see Winchester and every other of our cathedrals safe. There are no dealers in cathedrals at present, and therefore no market prices to be engineered for the benefit of American millionaires.

NOW we want a few more patrons of modern art like M. ALFRED HIPPOLYTE CHAUCHARD, the great Parisian milliner, to collect the best of our modern paintings, sculptures, and other works of art, and present or bequeath them to the nation, so that we may have the British counterparts of the works of MILLET, COROT, TROYON, ROUSSEAU, DIAZ, DELACROIX, DECAMPS, and MEISSONIER that now become the property of the French nation. Only our benefactor should start without the dealers, if he is to carry into the acquisition of art treasures the business ability that he has exercised in his own trade.

THE value of the sites of our City churches is so great that we must be thankful for the preservation of the tower of St. Alphege, London Wall, which now seems to be assured. The Vestry have done well to awaken in time and to realise that the key of the situation is in their hands, so that, within reason, they can exact their own terms. Confronted as the diocese of London is with the difficulty of providing sufficient accommodation for the possible needs of growing districts in the outer ring, it is hardly to be expected that any Bishop of LONDON should hesitate to sacrifice an apparently unnecessary church within the City for the tempting price that it would fetch. It behoves the parishioners in vestry, therefore, in each case to see that all the ancient landmarks of art and worship are not cleared out of the square mile.

THE possibility of the winding-up of the Crystal Palace Company, and the consequent destruction of the building, is to be regretted, not only for the sentimental regard that one must feel for that destruction, but also for the loss of the valuable though little appreciated architectural courts and the excellent school of engineering that are now housed at Sydenham. This is another opportunity for a loud scream, but who is to do the shouting? We commend the job to the new Council of the Royal Institute, as they seem so proud of their business ability; and with their wonderful diplomacy no doubt they could induce the Civil Engineers to help.

FROM the *Exeter Diocesan Gazette* we learn that several of the churches in the Woodleigh Deanery have been the cause of anxiety to their custodians and parishioners in respect of the safety of the bells or their containing towers. At Aveton Gifford, Woodleigh, East Allington, Churchstow, Bigbury, Kingsbridge, and West Alvington the belfries and their contents have been examined and set right. Now other churches are supposed to require similar attention—South Milton, South Pool, East Portlemouth, Loddiswell, and Malborough are in terror. The whole movement through the district seems to be the result of a popular scare, which might easily have been avoided if the churchwardens had only fulfilled their duty and kept "ward" over the churches under their care. Bell frames, like arches, never sleep, and in course of time there must come a moment when the stress and strain of bell-ringing is too much for the tower or the frame.

ARCHITECTURE AT THE ROYAL ACADEMY.—IV.

THE drawing of "Additions to Piper's Corner, High Wycombe, Bucks," by Mr. L. ROME GUTHRIE, leaves one in doubt as to which are the additions and which is the original building, but at least we have a picturesquely grouped result with stately detail incorporated. "Hollingden, Woldingham," by Mr. HAROLD TRIMNELL, is a good design in timber and plaster, novelty and piquancy being obtained by the very sensible use for a summer country residence of a pillared verandah supporting part of the first floor external wall. Messrs. READ & MCDONALD'S "House in Kensington Palace Gardens" breathes the spirit of the locality, the atmosphere of Kensington Palace, and is an able exposition of the character of the architecture of the eighteenth century Royal suburb. "The New Formal Garden, Ardross Castle," by Mr. EDWARD WHITE, shows us in a good pencil drawing an admirable treatment of an approach series of terrace gardens leading up to the house.

Messrs. ERNEST GEORGE & YEATES in "Additions to Maristow, Devon," give us an example of the skill of Mr GEORGE in treating a Classic type of house, no less able than what we have come to regard as his usual manner. A well-drawn piece of detail is shown by Messrs. HORACE FIELD & SIMMONS in "Bank Premises, Okehampton—Detail," but if this is a sample the design of the whole building should be worth seeing. "Part of a Group of Twelve Houses, Hampstead Garden Suburb," by Mr. GEOFFREY LUCAS, is a charming piece of design for elevating the work of the speculative builder to the level of architecture. It is a good augury for the future of middle-class house building in England when we find artistic design becoming recognised as valuable for the sale or letting of the size of house that has hitherto been left to the mercy of the jerry-builder, with his soft-stone carving, tile hearths and mahogany newels and handrails. Good and picturesque design has enabled Mr. W. RUPERT DAVISON to occupy quite a large space on the Academy walls with his series of drawings in one frame illustrating "Bronygarth, Woldingham."

Mr. CHARLES F. A. VOYSEY has completely departed from his usual well-known and now, by plagiarism of his admirers, somewhat hackneyed treatment of rough-cast and green slate in his "House at Coombe Down, Bath." We have here quite a fifteenth-century looking house, reminiscent in detail of the Bishop's Palace at Wells—a stone building with stone slate roof arranged round a quadrangular court, with a real old-time hall, and yet sufficiently modern in its planning to make a liveable house, a happy combination of the spirit of mediæval and modern life. The charm of simplicity, which is one of the features of our domestic architecture in the present day is well exemplified in Mr. HAROLD KENNARD'S design for "The Gables, Amersham, Bucks," in which a home-like character of expression is obtained by the use of a big roof, with long ridge and dormers, that comes down to the level of the ground-floor ceiling and contains all the upper part of the house. Professor STANLEY D. ADSHEAD in his "Albion Terrace, Worthing," shows how the ordinary seaside lodging-house can be raised from the ruck. A plastered building, which, after all that may be said against compo and stucco, makes for dryness at the seaside, is relieved from banality by a moderate use of "Adam" type of ornament, whilst green verandahs and shutters, with a touch of red in the brick rings of bull's-eye windows, give a quite pleasing colour scheme. We first admired these houses in being, without knowing who had designed them, and are glad to find them represented on the Academy walls.

Mr. ARNOLD MITCHELL'S "House at Avon Dassett, Warwickshire," is a mansion of which, though no plan is given, we are able to realise from the coloured perspective picture that symmetrical elevations on each front have interest given by projecting pavilions or blocks, on the cleverly conceived device of an H-plan with an L added at the end of each arm. Messrs. JOSEPH MORRIS & SON in their "Cottage and Stable, Yateley, Hants," give us another example of simple and pleasant treatment with the upper storey in a tile roof over a plastered wall with red brick plinth. "The Rectory, Dinnington," by Messrs. SUTTON & GREGORY, is a good pen and ink drawing of a picturesquely grouped house with mullioned windows, an entirely suitable treatment for a country rectory, sufficiently mediæval to be quasi-ecclesiastical, sufficiently modern to be a twentieth-century house. Messrs. H. R. & B. A. POULTER'S "House in York Road, Camberley," is a quite modern design in plaster walls with wood-framed windows and picturesquely grouped red tile roofs.

Mr. GUY DAWBER, in his "Rebuilding of Nether Swell Manor, Gloucestershire," has used well his opportunity to produce a distinctly seventeenth-century type of big manor-house, quite indicative of the home of a rich and powerful lord of the manor. "New Residence, Bolton," by Mr. ARTHUR J. HOPE, is another instance of a house with a ground storey and a roof, the latter being covered with yellowish-green slates as indicated in the coloured perspective. "A Memorial Fountain" by Mr. H. INIGO TRIGGS is a beautiful piece of detail, shown in a delicate pencil drawing. It is therefore skied. Mr. ALBERT E. BULLOCK'S "Residence at Stroud, Glos.," is a big house designed for Mrs. HALL, in general good, but spoilt by a Brobdingnagian projecting gable over an octagonal bay. Mr. WALTER H. BRIERLEY'S "Exterior View of Bishopsthorpe Garth, York," is shown in an excellent pen-and-ink drawing by Mr. F. L. GRIGGS, and is a picturesque brick building of farmhouse type with pantile roof. Mr. THOMAS L. WATSON'S "Doorway, Ashfield House, Glasgow," is a good piece of detail, sufficiently original to be interesting, sufficiently conventional to be scholarly. "House, Stables and Cottage, Week St. Mary, North Cornwall," by Mr. W. CURTIS GREEN, is chiefly remarkable for its scheme of delineation, a study on grey paper of blue slate and Chinese white plastered walls.

Mr. MAURICE E. WEBB'S "New Staircase, Brockhurst, East Grinstead," is a pleasant piece of original treatment in arcaded wood work. In his "Gorse's Farm, Sussex," Mr. JOHN CASH has taken advantage of varied levels to make quite an interesting building, treated in the simplest way with plain brick walling relieved with tile hung bays. A pretty effect of a house next a river is seen in Mr. CHARLES E. MALLOWS'S "Proposed House near Abingdon," only one corner of which is shown in an excellent pencil drawing. Messrs. NICHOLSON & CORLETTE'S "King's House, Kingston, Jamaica," is, of course, in reconstruction after the late disastrous earthquake, and is apparently a study of a suitable treatment for a reinforced concrete building. "A Façade in Kingsway," by Mr. EDWIN L. LUTYENS, is quite the most successful design exhibited by this versatile architect in the present Academy, an office building, admirably treated with somewhat of a domestic character, but stately, and withal picturesquely interesting. Professor BERESFORD PITE'S "Bank in Euston Road" appears to be an added shop front extension to an old house, adjoining the recently erected insurance office by the same architect, and is clearly a study, marked by originality, of the possibilities of the Pompeian form of Greek architecture.

STUDENTS' DRAWINGS AT THE SOCIETY OF ARCHITECTS.

THE Society of Architects cannot be congratulated on the quality as a whole of the twenty-five sets of designs, or, rather, sets of drawings that have been received and adjudicated upon in the annual competition for their Travelling Studentship. True that the value of this is nothing like that of the Royal Institute prizes, but 25*l.* and a silver medal ought to have brought out a better set of drawings than is now exhibited at the Society's rooms. We understand that a selection of the drawings will subsequently be exhibited at various provincial centres; but the selection will have to be very limited if the Society and its students

Digitized by Google

are not to be a laughing stock in such centres as Manchester, Liverpool, Glasgow, and Edinburgh.

The subject set for the competition was "A secondary school, to be planned in conformity with the last building regulations of the Board of Education, and to accommodate 100 boys and 100 girls." The site was an easy one, with a frontage of 225 feet to the north-west, or rather west 30 degrees north, as shown, and we presume correctly, on the winner's plans, with side roads to the north-east and south-west of indeterminate length. The accommodation required was four class-rooms for each sex, headmaster's and headmistress's rooms, assembly hall, the usual cloak rooms and lavatories, chemistry and physics laboratories for elementary and advanced students, with balance room and preparation room, lecture theatre, manual instruction room, cookery room, two art rooms, and two music rooms.

Some students seemed to have but the most rudimentary notions of what a secondary school should be like, and we hope that all the competitors, without exception, will carefully study the paper on the subject read before the Society by Mr. G. TOPHAM FORREST. A criticism on all the drawings submitted has been printed by the Society, but we think they should go further and invite all the competitors to attend under their direction a class of design presided over by a competent instructor. A very large number of the competitors seem to possess but the faintest idea of what design in architecture really is, either as regards plan, composition, or detail.

Amongst the faults very generally to be found in the designs are the bad or improper lighting of the art rooms, the non-isolation of manual instruction-room, cookery room and music rooms, and right-hand light to class-rooms. These faults clearly do not always proceed from an ignorance of what is required, but from an insufficient skill in planning to attain the desired ends, as witness the performance of the *naïve* young gentleman who labels his windows on faces at right angles to each other "north light." He does not designate the aspect of the windows in his art room on the opposite wall to the supposititious "north light."

As the Society has, as we have already said, published a criticism on all the sets of drawings, we do not propose to follow them in this, or to repeat what they have already said. Our remarks on the individual designs are therefore supplementary to those of the Society.

The winning design, by Mr. C. H. HUDSON, has the art rooms on the west 30 degrees north aspect, and would therefore in summer time get a share of the late afternoon sun. Although in the main well drawn, the detail shows a lack of skill in draughtsmanship, the cartouch and amorini over the principal entrance being quite beyond the author's skill. There is a sad lack of knowledge of detail, the exaggerated frieze and diminutive architrave of the entablatures, for example, being variations from the orthodox that have no prescience of genius for their justification.

The design placed second, by Mr. G. LL. EVANS, like the winning one, has the art rooms with the almost western aspect, and moreover quite insufficiently lighted by small windows and skylight with a tunnel shaft that would make the lighting not only feeble, for an art room, but, what is worse, unequally disposed. The balance room is too far from the laboratory. The detail of No. 3 is one of the best bits of drawing in the room, but such faults in planning as a long lecture-room with a through traffic route across the middle, manual instruction and cookery rooms in the main corridor, are hopeless. The elevations of No. 6 with a little more knowledge and experience might have been made comparatively quite decent in the present company. The detail of No. 11 is good, but his design lacks strength and repose. No. 20's plan might easily be made very much better—that is, it has the elements of a good one.

The Royal Sanitary Institute and Parkes Museum will be removed to No. 90 Buckingham Palace Road, S.W., after June 24.

STEELWORK.—XI.

By C. V. CHILDS, A.M.I.C.E.

SHOP practice varies somewhat in its methods in England and America; in fact, the different means employed in cutting up the sections, especially the joists, alter the whole system of obtaining the steel from stock. In England the rolling mills, as soon as the material is rolled and whilst it is red hot, cut the joists into "stock" lengths by means of the hot saws; owing to the metal being sawn hot and the hot saws not being suitable for accurate work, exact lengths cannot be cut in this way. The long lengths of the joists as they come from the rolls are therefore cut up, either into lengths slightly longer than those on order for special work, or else into a certain quantity of approximately even foot lengths ranging between the minimum and maximum likely to be required for the various sections. These then pass into stock and replenish the stockyards of the constructional works. Probably in nine cases out of ten these lengths would have to be cut again on the cold or milling saws, either to dead or some intermediate lengths. The result of this system is that in many cases constructional firms will quote two separate prices, one for taking from stock and the other for delivery a certain time after the material is obtainable from the rolling mills. Taking from stock entails what is known as "cutting and waste"; perhaps a quantity of one section is required of, for instance, a length of 20 feet 6 inches; the works have in stock a few lengths each of 21, 22, 23 feet, &c. In order to supply what is necessary, the works have to cut up these lengths into the required 20 feet 6 inches, entailing a waste of from 6 inches to 2 feet 6 inches on each piece. Even then perhaps they may not have a sufficient number in their own yard and may be compelled to purchase either from the rolling mills or other constructional works' stock, or else wait until the date that that section is put down for being rolled on the rolling mills' programme, this being generally arranged according to the amount of that section there is on order at the mills. All this means delay in regard to delivery, and this delay is not always entirely the fault of the contractor, but should be put down to the system of the rolling mills cutting up their sections into stock or even foot lengths. Even for a large building the contract for the steelwork is not usually let more than a week or two before the steelwork for the ground floor is required; consequently the steelwork for this floor, and in nearly all cases for the first floor as well, has to be taken out of stock. If the steel contractor could be given more time in which to arrange for obtaining the plain material, there would not be so many complaints in regard to his being the cause of stopping the work of the other building trades; there is certainly some excuse for him until the ground and first floor steelwork is erected, but after that there should be none whatever. This system of cutting to lengths should really be taken into account by the quantity surveyor, there being two prices, one for cutting and waste which applies to material from stock, and the other for cutting to exact lengths at the rolling mills; the first should apply to the ground and first floors' steelwork and should appear in the quantities as so many cuts each on the various sections; the second should apply to the upper floors and appear in the quantities as a price per ton.

In America the whole system is different; the constructional shops' stockyard contains very little material but what is actually on order for special contracts. The small amount of material that is immediately wanted is obtainable from the rolling mills' stockyard, the remainder can wait until the rolls go in. As the material that is being rolled for stock comes from the rolls, one crop end only is cut off and the long length of probably nearly a hundred feet passes into the stockyard. This is then cut up to the lengths on order from the constructional works, by means of quick-cutting cold saws. The circular saws are about 4 feet in diameter, and run at about 4,000 revolutions a minute; the friction between the saw and the section that is being cut causes the saw to melt its way through the steel. Nearly all the joists in a steel frame building require to be cut to exact lengths; as these saws are not absolutely accurate, it is the usual practice to cut the joists about ¼ of an inch short; standard sizes of angle cleats are depended on for connecting the joists to the girders; the exact length is made up by allowing the cleats to extend about ⅛ inch beyond the ends of the web of the joist.

This does not make as neat workmanship as cutting the joists to exact lengths on the milling saws; but for building work, where the steelwork is to be buried out of sight, so

Digitized by Google

long as the strength is there, a beautiful finish is hardly requisite.

If the English rolling mills would adopt some such system of keeping in their own stockyards the long lengths as they come from the rolls it would always be possible for the contractor to procure the exact lengths he requires by paying the small extra cost of about five shillings per ton direct from the rolling mills. The stock reserve would then be located at the mills, obtainable at short notice; it would save the contractor having to carry a large stock of sections at his own works, some of which may represent dead capital for even years; there would not be the everlasting problem of how to cut up material on order to the least amount of waste; cutting would be cutting only and not cutting and waste; the waste ends would not have to find their way back to the mills, but would be there ready to go back into the furnaces; and finally, the main cause of all the delay that now occurs in getting the steelwork delivered at the site would be eliminated and the cost of steelwork would be reduced.

After the material is cut to lengths the next operation is to punch or drill the holes. Here also there is a difference between English and American practice.

For the better class of work in England the specification calls for the holes to be drilled; as before pointed out, there is a much larger proportion of heavy compound girders in English than in American designs, consequently English shops are better equipped for dealing with this class of work. English constructional engineers find it is easier, and that there is less handling of the material, to drill the flange holes for the compound girders in one operation, by means of batteries of radial drills.

For all other work, such as holes in angles and plates for plate girders, &c., punching is undoubtedly cheaper, and punching does not distort these sections as much as it does the joists, which generally require to be straightened after the flanges have been punched. For the best American work it is usual to specify that the holes must be punched $\frac{1}{8}$ inch smaller than the required diameter, and rhymed out to its full size, which is done by means of pneumatic drills.

For connections this is better even than if the holes were drilled; the connecting members can be assembled and the rhymer passed through, thus ensuring perfect alignment of the connection holes.

Notching the flanges of the joists, or, as it is termed in America, "coping," is rather a troublesome operation; it is usually performed in England by making a cut with the cold saw through the flange and cutting out the web by hand with a cold chisel, another method is to mill out the metal by means of a special milling machine; this makes a beautiful finish, but is a slow and costly process. In America this work is done on special coping or shearing machines; one-half the flange is sheared off, then the other half; this leaves the web extending to the full depth of the joist, which is then laid on its side and the web portion is sheared off on the bevel to fit into the joist, to which the notched joist is to be connected. The whole operation takes but about a minute. The writer once adapted one of Messrs. de Burgh's punches to do the notching according to the American method; this machine could notch ordinary sized joists at the rate of 40 notches an hour, and was capable of notching the largest sized joists; for these latter, however, the cut with the cold saw and the hand chisel is probably as good a way as any; but where works have a large amount of notching to do, such as cross joists, a smaller machine, capable of notching joists up to 10 inches deep, would probably be a good investment.

After the fitting work is done, there comes the question of painting; the safest covering to specify is two coats of linseed oil, either raw or boiled; this forms an elastic transparent skin, which does not conceal defects of workmanship in the same way as an ordinary paint does; no paint of course is of much good unless the steel is first cleaned of scale, otherwise when it flakes off the paint goes with it. As a general rule it is worse than useless to specify any paint that contains pigments, such as red oxide of iron. The reason is this—freshly painted steelwork is slippery, and for that reason dangerous stuff to handle in slings when loading it on carts; the object of the contractors' painters is to make the paint dry as quickly as possible, so as to be able to send it out of the yard; to do this a large amount of drier, such as benzine, is often mixed with the paint. This certainly makes it dry rapidly, but the quicker it dries the less good it is as a protective covering for the steel; such a paint will begin to flake off almost as soon as it is dry, then it is useless to apply linseed oil or a better class of paint unless the first coat of poor quality is scraped off.

After the steelwork is erected and bolted in position just sufficiently to keep it in its place, the practice in America is to have gangs of riveters following the erection gangs, who rivet together the whole of the work; bolts have given place to rivets for all steel framed buildings of any great height. In England this is rarely done, and the connections are almost invariably bolted together. There is not the same necessity for rivetted connections in an English building. The object of rivetting the connections of the steel framework is to give it rigidity; this is most important in a very high building, whose rigidity is almost entirely dependent on the steelwork, and cannot rely to any great extent on that supplied by the walls, which are only external ones, and usually but a brick and a half thick. In the case of English buildings, their height is comparatively small, and the walls substantially thick; so that the walls are quite capable of supplying all the rigidity necessary. Moreover, in America the joist connections depend mainly on angle cleats connecting the web of one joist to the web of another, the bolts or rivets being in shear; hence rivets are preferable to bolts. The practice in English work is rather to make the joist bearings take their seating steel on steel—for example, cross joists rest on continuous shelf angles, and bearer girders are carried on brackets, so that the bolts are seldom subjected to a shearing stress. Cases occur sometimes in English work where it is advisable that the work should be rivetted together in situ, the reason being almost invariably a desire for providing extra rigidity in the structure.

Comparisons are said to be odious, and comparisons between English and American practice have been frequently made in these articles, without, it is to be hoped, wounding any susceptibilities. Each country has evolved its own methods in regard to steelwork design; evolution is governed by environment, and generally works out its own salvation along the lines that suit it best.

America may claim the credit for devising the skeleton framework; in her case it was an absolute necessity in order to satisfy her lofty ideals in architecture. In this country steelwork takes a lower position; it is not so much an absolute necessity, but rather a luxury in architecture. It provides a fire resisting, or rather a non-combustible, material for the floors; it enables the shop-keeper to display a wide and uninterrupted expanse of shop front; it relieves the architect of most of his constructional worries, for walls and chimney flues become independent of open spaces in the floors below; all this it may do and more, but it is very improbable that the typical American steel framed structure, that is to say, a self-contained framework in itself, will ever become the standard method of construction for English buildings. For isolated buildings especially of the warehouse class there is no question as to the suitability of the steel framed building. Where, however, there are such things as party walls, and party walls may mean internal walls dividing a building into restricted cubical contents, and the thickness of these walls remains regulated by our Building Acts, as indeed they are likely to do so, then it is better to consider these walls as a constructional feature of the building rather than as so much dead load to be supported on steel girders and stanchions.

It is a very simple matter to strike a balance between the cost of brickwork and steelwork; for example, take a 20 feet length of wall as required under the present Building Act for an ordinary six-storeyed building; such a wall would carry at each floor level about 5 or 6 feet depth of floor bay at either side of it without exceeding the allowable safe pressure on the brickwork. Under the proposed new Building Act the reduced thickness would save about $2\frac{1}{2}$ rods of brickwork, worth about 40*l.*; in order to effect this saving a steel framework would be required costing about 110*l.* in girders and stanchions; hardly an economic proceeding. When, however, the building rises to ten or twelve storeys, then the balance sheet would show a very different result; in fact, it is then that steel skeleton construction becomes almost imperative.

It will be generally found, where different countries adopt different methods, that these methods are those most suited to the local requirements; this undoubtedly is true in regard to English and American practice in steel construction.

The previous articles in this series, which is now completed, appeared on January 8, 15 and 29; February 5 and 19; March 5 and 19; April 2 and 16; May 14.

THE HITTITES.*

OUR subject for this lecture is the Hittites, and at the outset I shall beg that indulgence which you will readily accord to the treatment of a new science dealing with an unknown people using an unknown script and language. The subject, however, is not altogether new, so that a lengthy introduction is unnecessary; but inasmuch as it seems to be ten years ago since the problem of the Hittites was last dealt with before the Royal Institution by Dr. Wright, we may refresh our memories by briefly reviewing the circumstances under which that problem arose. Psychologically I suppose that is the right preparation for what will follow.

There were four sources of evidence:—(1) The monuments and archives of the Pharaohs recounting their warfare with the Kheta and their allies in the North of Syria; (2) the references to the Hittites in the Old Testament, vague at all times, particularly in the Book of Genesis, but more readily intelligible after the settlement of the Israelites in Canaan; (3) the later records of Assyria, giving glimpses of the final overthrow of the Hatti; and (4) a series of prehistoric and unexplained monuments associated with peculiar hieroglyphic inscriptions in the North of Syria. It was in pondering upon these materials that Professor Sayce came to the natural conclusion that the unexplained monuments in question must be those of the Hittites, and finding the same hieroglyphics even in the west of Asia Minor was led, in 1876, to his dramatic inference of a forgotten empire, an Oriental Power rivalling those of Egypt and Assyria. It was a brilliant hypothesis, imaginative and scholarly, smiled upon indulgently by the age of over-cautious and easier destructive criticism that is happily passing by, but confirmed none the less thirty years afterwards—that is, two years ago—in its main features by the discovery of Hittite archives at Boghaz Keui, in the north centre of Asia Minor, archives including diplomatic correspondence with the Courts of Babylon and of Thebes. The discoveries of Layard and Schliemann, Mariette and even of Champollion have not had effects more reaching than will these.

As Professor Sayce has published the results of his reasonings, and the main features of the problem are well known, we will select for illustration from this preliminary material only some few details of history and archæology that will be of special interest to us in the course of our inquiry.

Historically, our first reference to the Kheta in the eighteenth dynasty is in the twenty-third year of Thothmes III., B.C. 1474, when they are referred to as the great Kheta, or Kheta the great, in distinction to a possibly smaller element also called Kheta among the Hittite peoples. They were then seated in the North of Syria; but looking back, there are earlier traces of the gathering and oncoming of the various tribes in the North of Syria, who later together formed the Hittite confederacy, under the leadership of the Kheta chieftain. (It is in this sense, by the way, that we use the word Hittite.) Thus in his twenty-third year we find the same king addressing his army before Megiddo, saying:—"That (vile) enemy of Kadesh has come and entered Megiddo, having associated with himself other chiefs of all the lands previously obedient to Egypt as far as Naharina."

The last-named country, seemingly somewhere on the plains between Aleppo or Aintabb and the Euphrates, is mentioned several times previously, even as far back as the "reign of Thothmes," about B.C. 1550; for we find in the biography of Aahmes at El Kab an account of an expedition to repress a rising there, when the narrative says, "We found that enemy who had plotted conspiracy." So that the land had been conquered earlier, though no Egyptian record of the fact has come down to us.

Whoever "that enemy" may have been, we have reason to feel the Hittite presence, even upon the frontiers of Egypt, at a much earlier date—namely, in the twelfth dynasty. The reading "Kheta du Stela," C 1, in the Louvre, has not been explained away, in spite of the wrigglings of philologists. And the strangers immigrant into Egypt depicted on the tomb walls at Beni Hassan are witness to the presence in South Syria of a culture influence which has one peculiarity in common with that which typifies the Hittites—*e.g.*, the turning-up shoe and several features nearly related, as the embroideries and the lyre. This presence of an advance guard, settled already in South Syria, would explain many of the difficulties of the references in the Book of Genesis. However that may be, from the time of Thothmes III. onwards the ever-renewed struggles of the Pharaohs with the Hittites are matter of common history. In the time of Amenhotep III. Egypt made an alliance with the Mitani (east of the Euphrates), who report in one of the Tell El Amarna letters a struggle with the Khatti. This struggle was destined to continue, but we learn from one of the recently discovered tablets of Boghaz Keui that it was not until 100 years later that the Mitani country was absorbed into the Hittite power. Further letters in the following reign, that of Khuenaten, indicate the leaguing together of the principalities of Syria with the Kheta, who from the North of Syria had gradually spread their influence south until, in 1375, they were finally established in Kadesh, in the North Lebanon; indeed, a Kheta leader addresses a letter in a foreign language to Egypt about that time.

The monuments of Seti and Rameses the Great take up the story. The offensive and defensive alliance of C——, B.C. 1300, did not altogether end the struggle, for Rameses III. claims to have made a living chief of the Kheta captive; but the circumstances of these later wars are different. It is suggested, indeed, by the name of the mother of Psamtek III. in much later times, viz., Ti-eut-Kheta, that these may have been colonies of the Kheta in Egypt for several centuries. With regard to the treaty of peace, I will refer to one of the seals, which is described as the image of Sut—— embracing the great chief of the Kheta. This recalls, as the late Italian scholar De Cara pointed out, one of the sculptures of Boghaz Keui. These sculptures we shall consider in the light of recent discoveries, but the suggestion at the time was far-seeing and noteworthy. It is also remarkable that the other seal is described as representing the image of Sut—— embracing the great Queen of the Kheta, who was priestess of the god.

From other monuments of Rameses II. we glean much as to the racial types of the Hittite confederates, their arms and chariots and their fortresses. The frontier stronghold of Kadesh is several times represented, showing us the extra mural towers which were used for purposes of defence, giving an enfilading fire against attack. This type was a definite stage more advanced than the Egyptian fortresses that we know, and will be of interest to compare these pictures with plans of Hittite fortresses that we shall consider in the next lecture.

Other temple sculptures (or mural decorations) show us the Hittite captives and warriors, in which many types may be made out, while several are conspicuous. These types may be compared with those of Hamath, Kyzyl Hissar, Eyuk, Kartal. Egyptian evidence of confederacy is confirmed by the Biblical references in the later books. Thus, "All the kings of the Hittites" (I. Kings). Earlier reference (Genesis) places Hittites in South of Palestine around Hebron; intermarriage was frequent. The words, "Thy father was an Amorite, thy mother a Hittite" (Ezekiel xvi. 3, 45), are now full of a new ethnographical importance. This may well have been an earlier settling of Kheta or some branch of the Hittite people, coming by way of the mountain ranges fringing the seaboard of Syria, where the types mostly survive.

Assyrian monuments (Kheta) do not appear until 1100, but the Hittite archives make mention of Assyria 200 years earlier. At the time of Tiglath Pileser, Lheta, in the Orontes, and Carchemish, were some of their cities. Sargon (721-4 B.C.) finally overcame the Hatti.

* Abstract of an illustrated lecture delivered at the Royal Institution by Professor John Garstang, B.Litt., M.A., F.S.A., John Rankin Professor of Archæology, University of Liverpool.

HERTFORD COLLEGE.

By S. G. HAMILTON, M.A.

THE present foundation of Hertford College dates only from 1874, but the College is the heir of two halls which have successively occupied its site. The earliest of these, Hart Hall, was established between 1280 and 1300 by a certain ELIAS OF HERTFORD, from whom the College derives its name and its arms. The device of the hart's head with the cross between the antlers figured on the seal of ELIAS, and probably appeared also on the gate of his Hall, which seems to have been known from the earliest times as *Aula Cervina* or *le Herthalle*.

In 1312 Hart Hall was purchased by WALTER STAPELDON, Bishop of Exeter, and for a time was actually the home of his new foundation, soon removed to the present Exeter College; later WILLIAM OF WYKEHAM'S scholars were housed in its buildings while New College

Digitized by Google

was in course of erection. After their migration the Hall remained for a long period a dependency of Exeter College; the scholars of Exeter resorted to Hart Hall for their lectures and performed their academical exercises in common with the scholars of the Hall, under a Principal, who was always the nominee, and generally a Fellow, of the College. This condition of affairs lasted until the time of PHILIP RONDELL, who was Principal 1548-99. Like the majority of his predecessors, he was a Fellow of Exeter, and during the first period of his rule no doubt acted, as they had done, as the delegate of the College in charge of what was described as "their tenement or house ordained for the advancement of learning, commonly called Hart Hall." But when Exeter College, under its new charter of 1566, began to receive commoners as well as scholars within its walls, and to provide for their tuition at home, Hart Hall gradually ceased to be resorted to by Exeter scholars, and by the end of RONDELL'S long principalship had pretty well achieved its independence.

It is natural that the earliest extant buildings of Hertford College should date from this important epoch in the development of Hart Hall. RONDELL built the north-eastern corner of the existing quadrangle, including the old Hall, which was still the dining-hall of the College as late as 1888. It is now the library, and, it may be hoped, will still serve some useful purpose in the College when the library is transferred, as it soon must be, elsewhere. The next addition to the buildings, which still survives, is the Jacobean block immediately opposite the gate. This was built by Dr. PRICE, RONDELL'S second successor, as a lodging for the Principal, a purpose which it served until 1805. The top storey, however, with its gables, so happily designed as to be easily mistaken for a part of the original building, is an addition of the last century, for which the credit is due to the munificence and good taste of Dr. MACBRIDE. The subsequent buildings of Principals ILES (1622-33) and THORNTON (1688-1707) have been demolished, though the kitchen of the former continued in use as long as RONDELL'S dining-hall; and the gates of the latter still serve their original purpose, though hung in a new archway.

In 1710, when Dr. RICHARD NEWTON, the founder of the first Hertford College, became Principal, Hart Hall held the first place among Oxford halls, and rose to still greater eminence under the care of the new Principal, who established in it a scheme of teaching and discipline which he fondly hoped would be a model for the reform of all other halls and colleges. But the great ambition of his life was to make his scheme permanent by procuring the incorporation of his Hall as a college. With this object in view he built a chapel, which was consecrated in 1716, and has been in use until the present time, when it is about to be replaced by a worthier edifice; he built also the south-eastern angle of the College, part of which still remains. By these buildings the southern side of the quadrangle, until then void, was filled in; and with these additions to his Hall, and his code of statutes, Dr. NEWTON applied for a charter of incorporation for Hertford College in 1723. He met with bitter opposition from many quarters, especially from Exeter College, the owner, it must be remembered, of a large part of the Hall. A strong party among the Fellows, led by Dr. CONYBEARE (who became rector in 1730), succeeded in obstructing the progress of NEWTON'S foundation for nearly twenty years. NEWTON'S persistence, however, triumphed in the end, and the new College received its charter on September 8, 1740.

NEWTON had had a hard struggle to found his College, and the College had a hard struggle to maintain its position; for NEWTON, in his scheme of reform, aimed especially at economy, and his method of enforcing economy was to keep his College poor, that it might not be extravagant. The endowment originally proposed would have been insufficient, even if it had been completed; but it never was, and the College was strictly forbidden to accept more. In the circumstances it is very much to the honour of Dr. NEWTON and his successors that the College did actually exist with credit for fifty years. Its most flourishing period was the principalship of Dr. DURELL (1757-75), in whose time CHARLES JAMES FOX matriculated. Under DURELL'S successor, Dr. HODGSON, it steadily declined, and after his death in 1805 no Principal was appointed.

Meanwhile in the shadow of Magdalen College, almost from the time of its foundation, had been growing up a Hall which took its origin from the Grammar Lecture founded by WAYNFLETE for the benefit, in the first instance, of his own foundation. But the lecture attracted other students, who, though not members of the College, occupied buildings belonging and adjoining to it. This small community, existing at first on sufferance, gradually won its way to the position of an academical hall, a position which was fully established by the time that THOMAS HOBBES matriculated as a member of Magdalen Hall in 1601. But its dependence on Magdalen College was unquestioned, and it was a surprise to the Fellows of Magdalen to discover in 1694, after litigation, that they had not legally even the right, which they had exercised for two hundred years, of appointing the Principal of the Hall. By the decision of the Court of Common Pleas, Magdalen College found that a part of the site intended by their founder for the use of his foundation had become the property of the University in trust for a Hall which WILLIAM OF WAYNFLETE had never thought of establishing. So Magdalen Hall continued to occupy its buildings, of which nothing now remains but the graceful turret which is incorporated with the new St. Swithun's buildings of Magdalen College.

After the failure to appoint a new Principal of Hertford on the death of Dr. HODGSON in 1805, the College was falling rapidly to ruin. It was still supposed to exist as long as the eccentric RICHARD HEWITT, the last surviving Fellow, continued as Vice-Principal; but no degrees were taken from the College later than 1810, and HEWITT'S fellowship expired in 1814. The vacant rooms were invaded and occupied by all manner of queer characters, until it became necessary that something should be done to preserve the buildings from further waste. In the end an inquisition was held on May 4, 1815, by Commission under the Great Seal, by which it was found that the College had become dissolved on June 28, 1805, one month after Dr. HODGSON'S death, and its property escheated to the Crown. The fact was that Magdalen College had seen its opportunity to recover what it had lost in 1694. The inquest on the defunct Hertford College was but the first step openly taken to carry out an arrangement by which Magdalen Hall was to be transplanted to the site of Hertford, while Magdalen College was to recover possession of its former property. An Act of Parliament sanctioned the scheme, and the dissolved College was immediately afterwards granted by Letters Patent to the University in order to carry it out. A disastrous, but in the circumstances rather opportune, fire hastened the migration of the Hall. The greater part of the old Magdalen Hall was burned down on January 9, 1820. The first stone of the new buildings on the Hertford site was laid on May 3 the same year, and Magdalen Hall took possession of its new home two years later.

The new buildings of Magdalen Hall consisted of the two blocks of equal size facing the Schools tower which still form the front of Hertford College, but they were then connected, not as now, by the College Gate and Hall, but by a stone screen with an archway in the middle, in which THORNTON'S gates were hung. The southern block was, as it now is, the Principal's house; the northern block occupied by rooms. These buildings, with the addition of NEWTON'S chapel and angle at the south-east, Dr. PRICE'S buildings on the east side. RONDELL'S hall and buttery and Dr. ILES'S kitchen on the north, formed the quadrangle of Magdalen Hall as it stood in 1874. In that year the cherished desire of Dr. MICHELL, who had succeeded Dr. MACBRIDE as Principal in 1868, of turning the Hall into a College was realised through the munificent endowment provided by THOMAS CHARLES BARING, M.P. for South Essex.

Digitized by Google

The Act of Parliament by which the present Hertford College was constituted received the Royal assent August 7, 1874; but for more than ten years the new foundation had to content itself with the buildings which had been vacated by Magdalen Hall. It was not until 1886-8 that the first step was taken to provide the College with adequate accommodation. It was then that the new hall was built, with the College gate underneath, in which the doors set up just two hundred years before by Principal THORNTON have found, it may be hoped, their final resting-place. The carving of the drinking stag above them is also reproduced from THORNTON'S gate. By this building the gap in the frontage of the College towards the Bodleian was filled, and the whole front made more ornamental, though the severe simplicity of style, of which Dr. NEWTON had set the example in his angle, is still maintained. Inside the quadrangle the construction of the staircase leading to the hall distantly but distinctly suggests the famous staircase of the Château of Blois.

Mr. T. G. JACKSON, who has borne so great a part in making the outward appearance of modern Oxford what it is, was the architect of the new hall, and it is from his designs that all the subsequent new buildings of the College have been erected. In 1889-90 a large part of the northern side of the quadrangle, containing Dr. ILES'S kitchen, and the mean entry, which had served as the College gate, was demolished, and in its place rose the block of rooms towards New College Street. Soon afterwards the College acquired from the City the site of the old City Ditch on the other side of the street, and from Merton College a piece of ground behind this with a frontage upon Holywell; on this land two sides of what will eventually be a second quadrangle have already been built, and building is still in progress. But the most interesting feature of this recent acquisition of the College is the octagonal fourteenth-century chapel of "Our Lady at Smithgate," the shell of which has been recently exposed by the demolition of the houses adjoining; the doorway, with its carved representation of the Annunciation, has never been hidden. This is the chapel in which, as WOOD tells us, it was the custom for candidates for degrees to "pray for the Regents" (who were to examine them) before entering the Schools close by. It is to be hoped that as much as possible of this interesting relic of mediæval Oxford will be preserved, enshrined in the new buildings with which it is to be incorporated.

Though this and much more remains to be done, the reconstruction at any rate of the older part of the College has now been completed by the erection of the new chapel, which is certainly one of the most pleasing and successful of Mr. JACKSON'S buildings.* The inadequate size of the old chapel built by Dr. NEWTON may be judged by the fact that the oak panelling and the marble pavement of the old have been found just sufficient for the ante-chapel of the new; but it is satisfactory that a place has been found for some memorial of the chapel in which Dr. NEWTON may be said to have laid the foundations of the first Hertford College.

ILLUSTRATIONS.

COMPETITION DESIGN FOR BANQUETING HALL AND BALL ROOM, FREEMASONS' HALL, LONDON.

THIS drawing was submitted with Messrs. ERNEST RUNTZ & FORD'S design in a limited competition for the rebuilding of Freemasons' Hall. This room was intended to adjoin the "Temple," as did the old one, but it is considerably larger, occupying an area of 8,797 square feet, including galleries, being 4,449 square feet in excess of the former hall.

In the main the plan is rectangular; it is divided into three squares, the central one surmounted by a dome 42 feet 6 inches in diameter and 46 feet in height, and having a recess with a gallery over on the east side. The end squares have segmental arched ceilings 38 feet in height, each with galleries, and the whole is decoratively treated in the style of the Renaissance and capable of subdivision by means of partitions into three banqueting halls.

* The new chapel was opened on October 7, last year.

OXFORD COLLEGE SERIES, HERTFORD.—ENTRANCE—INTERIOR OF HALL.

SEE article on page 381 by S. G. HAMILTON, M.A.

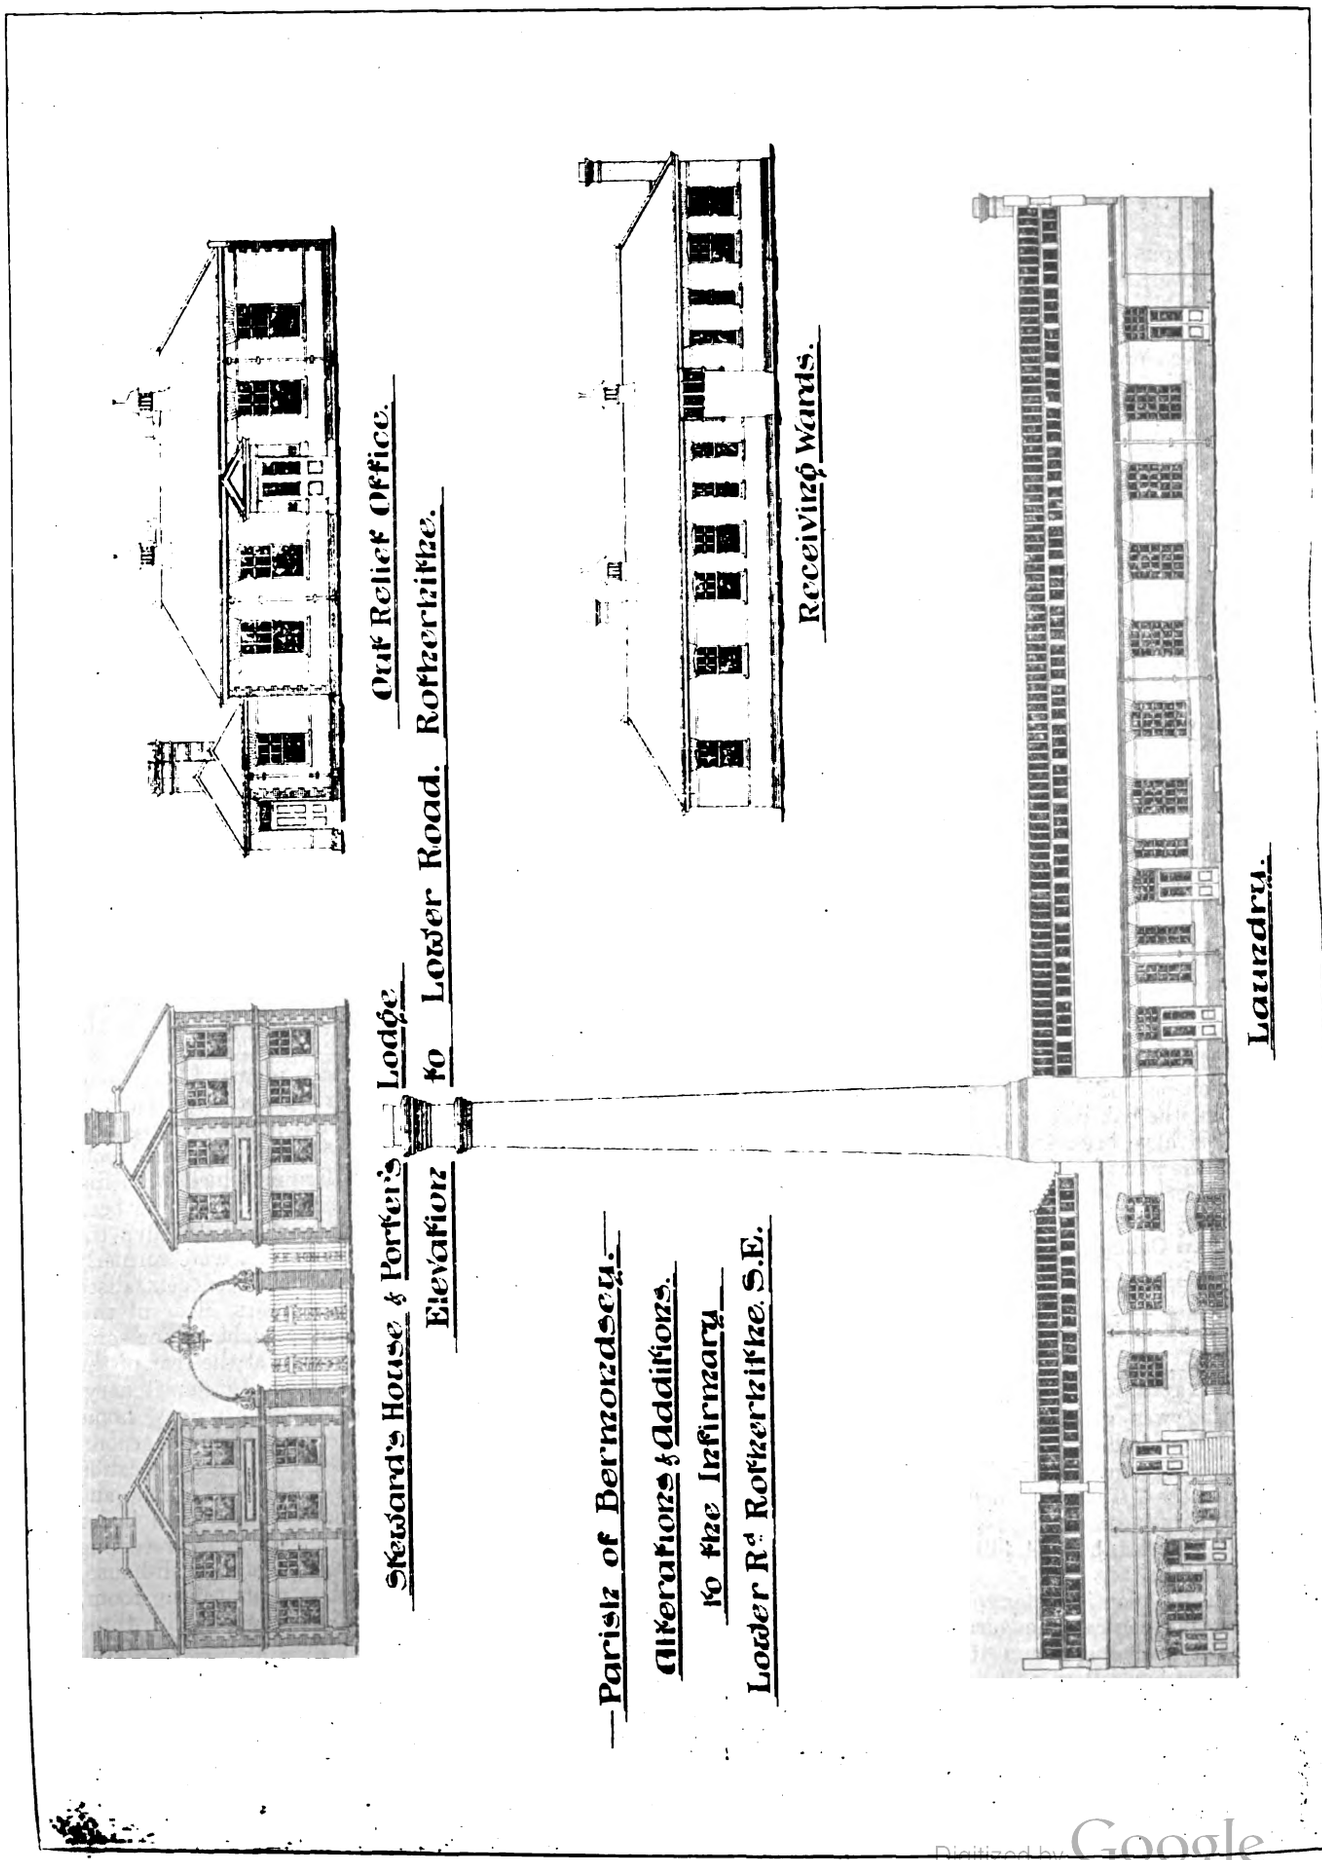
LODGE AND STABLES AT CHALFONT ST. GILES, BUCKS.

THIS is planned as a lodge and yard on one side and stable and motor house on the other. The materials are small-grooved Fletton brick lime-washed, and the roof is thatched with Norfolk reeds. The fittings inside cottage and stable are very simple; casements from Messrs. HENRY HOPE & SON, LTD. The architects were Messrs. FORBES & TATE.

HOUSE AT CHALFONT ST. GILES, BUCKS, FOR ARCHIBALD GROVE, ESQ., M.P.

THIS house is built of Dutch bricks and roof with old pantiles. The accommodation is ten bedrooms and four reception rooms. It is situated in the centre of a wood, and since the photographs have been taken the garden scheme has been begun. Messrs. AMES & HUNTER supplied the Dutch bricks and tiles. Messrs. HENRY HOPE & SONS, LTD., supplied the casements and door furniture. Messrs. FORBES & TATE were the architects.

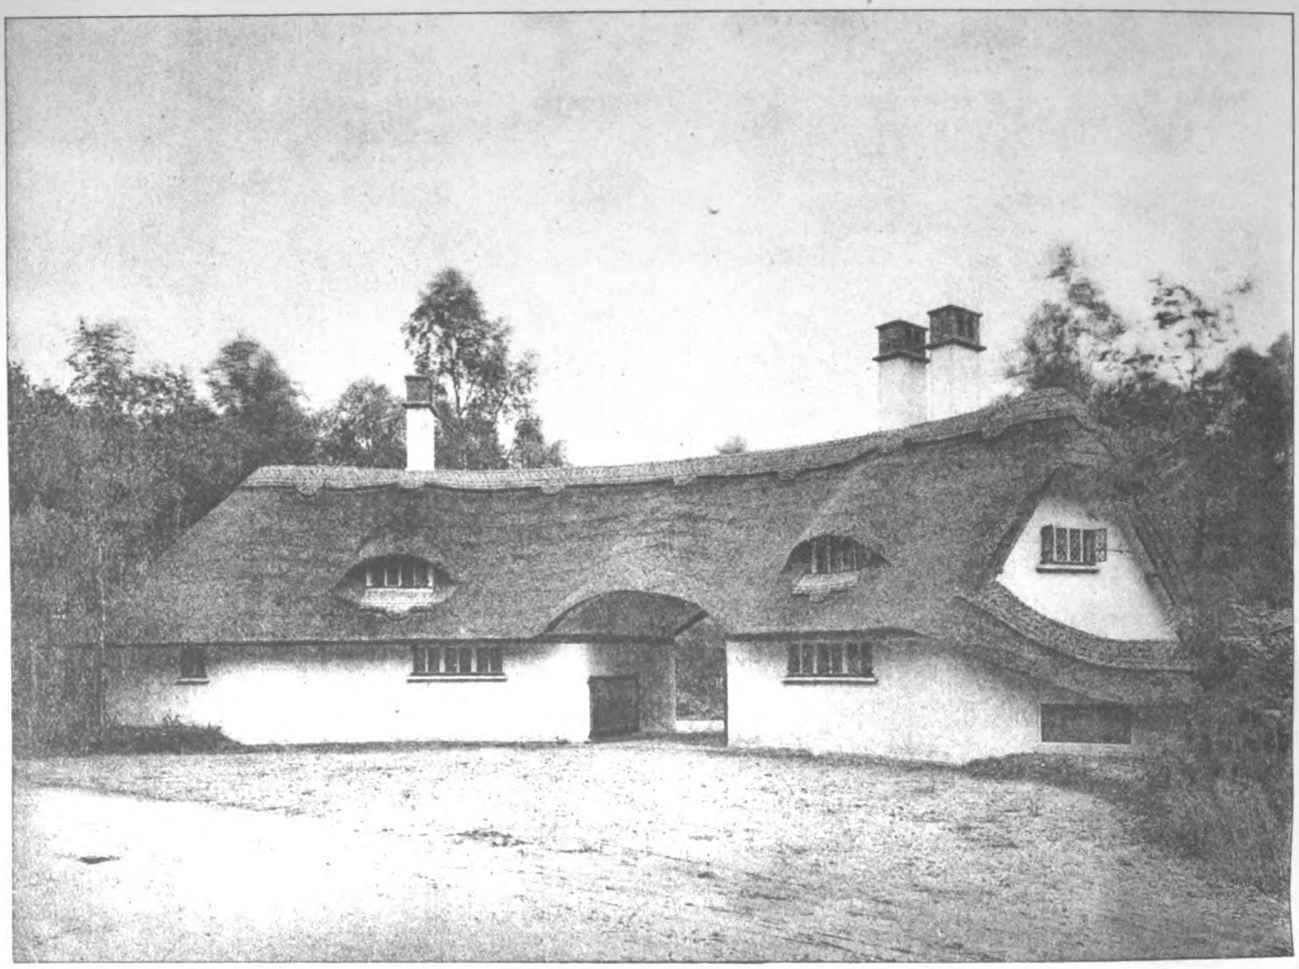
HOUSE AT CHALFONT ST. GILES, BUCKS, FOR J. EDWIN FORBES, ESQ.—NORTH ELEVATION—SOUTH ELEVATION.



THIS house was designed for J. EDWIN FORBES, of the firm of FORBES & TATE, the architects. It is in the middle of open woodland and is designed with large reception rooms and open-air loggia. The garden scheme was designed by Miss JEKYLL. The house is built in sand-faced bricks and roofed with old country tiles.

PARISH OF BERMONDSEY.—THE INFIRMARY, LOWER ROAD, ROTHERHITHE—SITE PLAN.

THE alterations which have just been completed to the Bermondsey Infirmary have been confined to the staffing and administrative portions of the institute rather than to the wards and patients' accommodation. The site plan illustrated shows the new work in hatched lines and the old work in solid black. With regard to the administration block, however, this plan does not show as clearly as might be desired the large amount of alterations made, which have been chiefly connected with enlarging the capacity of this part of the establishment in order to meet the extra demands made upon it by the increase in the work of the infirmary. Thus, the kitchen and scullery have been structurally enlarged and fitted up with extra and modern cooking apparatus. What was formerly the steward's and his clerks' offices have now been added to and converted into a nurses' mess room and a servery and china store. Rooms which were formerly used as store rooms of various kinds have now been cleared out and used as staff mess rooms. Thus the whole of the dining arrangements, which were formerly spread over several buildings, have now been centralised into the administration block. The first floor of this block has been altered and fitted up as cubicles for some of the staff. The old laundry, situated at the rear of the administration block, has been denuded of its machinery, &c., and refitted as a general store. The nurses' home has been enlarged by the addition of a new wing to accommodate twenty-eight nurses and also by a large recreation room. New bath annexes have been built to a male and a female ward building. The new laundry and boiler house contains, as will be seen from the plan, receiving room, foul linen wash-house, large general wash-house, drying closets, ironing and mangling room, airing room, delivery room, and office. The boiler house, with three 27-feet boilers, which supply the general heating of the institution, and coal store attached, the engine room, fitted with a MARSHALL'S horizontal engine and feed water heaters, &c., and the engineer's workshop, &c., complete this building. The new receiving wards contain male



Digitized by Google

and female wards, clothes store, bath rooms, &c. The building formerly used as a receiving ward has now been turned into an isolation ward block for male and female patients. The buildings fronting on to the main lower road are the steward's house and porter's lodge on either side of the main entrance gates, and the out-relief building. The engineer's house, as will be seen, is placed near the laundry. The well house opposite is built over a well 316 feet deep, from which water supply is obtained. The contract, for the sum of 41,785*l.*, has been carried out by Messrs. WALTER LAWRENCE & SON, of Canal Works, Waltham Cross; the engineering by Messrs. J. & F. MAY, of High Holborn; well and pumps by Messrs. BAKER & SONS; electric lighting by the Salisbury Electrical Engineering Co., of New Kent Road. The clerk of works was Mr. J. CARPENTER, and the whole of the works have been executed according to the plans and under the supervision of Mr. ARTHUR H. NEWMAN, F.R.I.B.A., F.S.I., of 31 Tooley Street, London Bridge, S.E., the architect to the Board.

THE SAXON TIMBER CHURCH AT GREENSTEAD, ESSEX. From a Sketch by ADRIAN HARDMAN.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

AT a business general meeting held on Monday last the officers, Council, and standing committees for the ensuing session were declared duly elected, in accordance with the scrutineers' report, as follows:—

The Council.

President.—Ernest George.

Vice-Presidents.—Professor Reginald Blomfield, A.R.A., M.A.Oxon., F.S.A.; Alfred William Stephens Cross, M.A.Cantab.; Edward Guy Dawber; James Sivewright Gibson.

Hon. Secretary.—Henry Thomas Hare.

Members of Council.—John James Burnet, A.R.S.A. (Glasgow); Max Clarke; William Adam Forsyth; John Alfred Gotch, F.S.A. (Kettering); Alexander Graham, F.S.A.; Edwin Thomas Hall; George Hubbard, F.S.A.; Henry Vaughan Lanchester; Edwin Landseer Lutyens; Mervyn Edmund Macartney, F.S.A.; Charles Edward Mallows; Ernest Newton; Andrew Noble Prentice; Halsey Ralph Ricardo; John Slater, B.A.Lond.; Leonard Stokes; Paul Waterhouse, M.A.Oxon.; Edmund Wimperis.

Associate Members of Council.—Alan Edward Munby, M.A.Cantab.; Professor Charles Herbert Reilly, M.A.Cantab.; Herbert Winkler Wills; Arthur Needham Wilson.

Representatives of Allied Societies.—Frederick Batchelor, A.R.H.A. (Royal Institute of the Architects of Ireland); George Bell (Glasgow Institute of Architects); George Thomas Brown (Northern Architectural Association); Arthur Stansfeld Dixon, M.A.Oxon. (Birmingham Architectural Association); Thomas Edgar Eccles (Liverpool Architectural Society); Mowbray Aston Green (Bristol Society of Architects) Percy Robinson (Leeds and Yorks Architectural Society); John Watson (Edinburgh Architectural Association); Percy Scott Worthington, M.A.Oxon. (Manchester Society of Architects).

Representative of the Architectural Association (London).—Henry Tanner, jun. [*F.*].

The Standing Committees.

Art.—Fellows: Walter Henry Brierley, F.S.A.; Edward Guy Dawber; William Flockhart; James Sivewright Gibson; Henry Thomas Hare; Professor William Richard Lethaby; Edwin Landseer Lutyens; Edwin Alfred Rickards; John William Simpson; Paul Waterhouse, M.A.Oxon.—Associates: William Henry Bidlake, M.A.Cantab.; Arthur Thomas Bolton; Sydney Kyffin Greenslade; Thomas Geoffry Lucas; Walter John Tapper; Septimus Warwick.

Literature.—Fellows: Alfred William Stephens Cross, M.A.Cantab.; John Alfred Gotch, F.S.A.; George Hubbard, F.S.A.; Halsey Ralph Ricardo; Professor Frederick Moore Simpson; Professor Ravenscroft Elsey Smith; Richard Phené Spiers, F.S.A.; Henry Heathcote Statham; Charles Harrison Townsend; Paul Waterhouse, M.A.Oxon.—Associates: William Curtis Green; Herbert Passmore; Arthur James Stratton; Harry Inigo Triggs; William Henry Ward, M.A.Cantab.; Percy Leslie Waterhouse, M.A.Cantab.

Practice.—Fellows: William Henry Atkin Berry; Max Clarke; Alfred William Stephens Cross, M.A.Cantab.; George Hubbard, F.S.A.; Sydney Perks, F.S.A.; Alfred Saxon Snell; Henry Tanner, jun.; Thomas Henry Watson; William Henry White; William Woodward.—Associates: Edward Greenop; Edwin Gunn; Edwin Richard Hewitt; Harry John Pearson; Horatio Porter, M.A.Cantab.; Augustus William Tanner.

Science.—Fellows: Harry Percy Adams; Max Clarke; Bernard Dicksee; William Dunn; Matthew Garbutt; Francis Hooper; Charles Stanley Peach; Sydney Perks, F.S.A.; Herbert Duncan Searles-Wood; Lewis Solomon.—Associates: Henry William Burrows, F.G.S.; Edwin Richard Hewitt; Alan Edward Munby, M.A.Cantab; Digby Lewis Solomon, B.Sc.Lond.; Ernest William Malpas Wonnacott; Ernest Alexander Young.

Auditors.—John Hudson [*F.*]; Charles Edward Hutchinson [*A.*].

The following members were elected:—As Fellows.—Arthur Thomas Bolton, Frederick Dare Clapham, Henry Arthur Crouch, John Stanley Heath, Edward Skinner (Ceylon), Percy Leslie Waterhouse. As Associates.—Donald Macpherson Gordon (Montreal), James Charles Morrell (Melbourne), Harold Beckwith Richards (Detroit, Mich., U.S.A.), William Arthur Rigg (London).

THE CONCRETE INSTITUTE.*

(*Concluded from last week.*)

THE cement introduced into these mills for the purpose of finishing was in a coarsely ground condition, having previously been dealt with by some form of preliminary grinder, during which process, owing to the friction entailed, the temperature of the material was raised to a point ranging between 140° and 160° Fahr. The friction due to the action of the attrition of the steel balls or flint pebbles against themselves, the sides of the mill, and the passing cement, caused the temperature in the tube mill to be still further increased, and it was at this point where moisture was introduced in the form of a regulated supply of steam, which still further increased the temperature and enabled it to be maintained at a point above 180° Fahr., preferably about 200° Fahr, at or above which temperature the operation is most successfully conducted, and the cement operated upon was made to take up uniformly throughout an amount of water, in practice about 1 per cent. or a little under, with which it combined chemically, and which could not be expelled except by ignition.

The thoroughness of the process will be realised when it was understood that the time of passage through the tube mill was about two hours, and that each particle of cement was being continuously submitted for that period of time to a moist atmosphere acting upon its surface, which latter was removed by the attrition of the balls or pebbles, exposing a fresh surface upon which a similar action took place, until the whole left the mill at a temperature which had been gradually increasing until the operation was complete. In this way the operation of exposure to moisture was accomplished at a temperature above the critical point necessary for the purpose, and in such a manner that no mechanical difficulties presented themselves in the blocking of the machinery or apparatus.

The facts mentioned in reference to the importance of carrying out the process at or above a certain temperature were not generally known.

Now let them return to the other method of retarding the setting time known to the ancients, i.e., the addition of gypsum to the product of the intermittent kiln during or after the process of grinding.

With this class of cement, containing already sulphates equivalent to about 1.5 per cent. SO_3, derived, as previously stated, from the sulphur compounds in the fuel, it was generally sufficient to add 1½ per cent. of gypsum to obtain a slow-setting cement; the effect, however, in most cases was only transient, as it was well known that the effect of aeration, even when the cement was packed, almost invariably resulted in such cement returning first to its original quick-setting condition before subsequently becoming slow setting, and largely inert through excessive exposure to the atmosphere. This peculiarity of cements slowed by gypsum had been the cause of much difficulty to the manufacturer, and many conflicting theories were propounded as to the cause of such reflex action.

A slow-setting cement containing 0.95 per cent. of SO_3, of which only 0.35 per cent. was added, retained this property of slow setting for long periods in commercial packages, as it was also known to do when stored in bulk.

It was difficult to give any definite chemical or physical explanation of the fact that the presence of as little as 1 per cent. of combined water in cement, which had been taken up at a high temperature, should not only in itself have the effect of appreciably slowing the setting time, but that when present in conjunction with even small percentages of gypsum the slowing effect of the combination was maintained.

The presence of 1 per cent. of combined water had also an enormous influence on the action of cement when tested for soundness under the boiling test, more particularly under the method invented by Le Chatelier and now usually adopted, by which method and with which apparatus it was thought the actual expansion of the cement could be measured.

By means of the steaming process described the proportion of gypsum required to be added to produce a slow-setting cement was much reduced, and if advantage were taken of the greater solubility of plaster of Paris ($CaOSO_3\ \frac{1}{2}H_2O$) over that of raw gypsum ($CaOSO_3\ 2H_2O$) the quantity of SO_3 introduced into a cement might be reduced to a minimum.

The author had referred to this subject on former occasions. Inasmuch as the effect of gypsum in retarding the initial set of cement depended upon the rapidity of solubility in the period immediately after the addition of water, and the quantity that could quickly be brought into solution (in which condition it was alone active), it followed that the form of gypsum having this property most developed would be the most effective. The quantity required to produce like results when plaster was used might be one-third less than with gypsum, and this was important in view of the known defects produced by the addition of gypsum to cement, more especially if the cement was to be deposited under water (more particularly sea-water) before setting commenced.

Le Chatelier, in a paper read at the meeting of the International Testing Association at Brussels, describing the behaviour of cements in sea-water, said:—"By introducing important quantities of calcium sulphate into hydraulic cements, it is possible to bring about their disintegration at more or less rapid speed; and as a rule destruction proceeds faster when the material is in the sea than when it lies under fresh water."

It was important, in view of the chemical action which was said to take place between the added sulphate of lime (gypsum) or the soluble constituents of sea-water, with the aluminate of lime in the cement, forming a compound said to be sulpho-aluminate of lime, that the amount of added gypsum should be kept as low as possible.

The action referred to by Le Chatelier was continually in evidence with all cements to which more than 2 per cent. of gypsum had been added to retard the setting time, when such cements were tested by the accelerated methods for determining the ultimate soundness, more particularly when they were subjected to the primary stages of that quantitative boiling test, which appeared in most specifications, introduced by Le Chatelier himself and which bore his name.

This test was designed with the object of detecting rapidly any inherent unsoundness in cement, so that a knowledge as to the constancy of volume of any cement might be obtained previous to its use in the work.

To those who had much experience in the orthodox working of this apparatus it was apparent that the conclusions drawn might frequently be entirely fallacious, and many perfectly sound cements thereby rejected, while others of doubtful quality for certain conditions of work were not detected. In adopting this test the fact seemed to have been entirely overlooked that many cements, more especially those containing over or about 2 per cent. of gypsum, were found to expand considerably during the primary immersion in cold water and might show but a slight further expansion during the second, or boiling, stage of the operation. Such cements would be passed as satisfactory by this test, and no doubt many would prove to be so, if allowed to harden before immersion in water. It would seem, however, that as at present conducted the test entirely failed to detect (unless a record of the expansion during the cold-water immersion was included) a cement containing an unsafe percentage of gypsum, which cement might be required for work where the concrete was of necessity deposited under water immediately after gauging.

The period of immersion before boiling stipulated in the Le Chatelier test was a very important factor in affecting the results, and appeared to be entirely arbitrary. It might be that certain cements, perfectly sound in cold and in boiling water, and especially those of a very slow-setting character, would fail to pass if boiled twenty-four hours after gauging, whereas at thirty-six or forty-eight hours, or even longer, the results might be perfectly satisfactory.

Now as to the causes of expansion of certain cements when boiled, this might be due to (1) an insufficient reduction and amalgamation of the raw materials, (2) incomplete or irregular calcination, or (3) a predominance of small unground particles of clinker in the finished cement. The Le Chatelier test was designed to guard against the results of such irregularities in the course of manufacture, and as regards points 1 and 2 was useful and effective, as unsoundness due to either of these causes might subsequently develop, causing disintegration. The expansion under these circumstances was probably due entirely to chemical causes, resulting either from unbalanced proportions of the raw materials, possibly also in an unsuitable mechanical condition, refusing to form during calcination a chemical combination of the same uniform character as would be the case if chemically balanced and thoroughly amalgamated; or, given a satisfactory raw material in all respects, the expansion on boiling might be due to the fact that during calcination the raw material, either wholly or in part, might not have been brought up to the requisite temperature at which the principal compounds constituting Portland cement were formed.

The expansion, however, due to the third cause, i.e.,

* A paper on the Setting of Portland Cement, read by Mr. H. K. C. Bamber on May 27.

Digitized by Google

the presence of unground particles of well-manufactured clinker, came under a different category, for the material causing expansion was of identical composition, and having the same chemical and physical properties as the finer-ground portions of the cement, which latter, per se, were entirely free from expansion when boiled. The cause in this case was rather more of a physical character than a chemical one, although it must be admitted that the hydration of the particles of clinker at the high temperature, which in the author's opinion was the cause of the expansion in this case, was a chemical process.

It was evident that the mere reduction of the clinker to a fine powder did not in any way change the chemical composition of the cement, and if any difference was noticeable under the Le Chatelier boiling test between a finely ground and the same coarsely ground clinker, the former being perfectly sound and the latter showing expansion, this expansion must be due to the action of water at a high temperature on these particles.

In the author's opinion the conclusions drawn from the results of tests under the Le Chatelier method, brought about through this latter cause, might be misleading, because it was assumed that these particles causing expansion consequent upon hydration at a high temperature would equally expand at normal temperatures, which had yet to be proved.

From experiments it would appear that the larger particles of clinker remaining even in a commercially finely ground cement, which were hydrated with expansion when in contact with boiling water under the Le Chatelier test, were also hydrated, and perhaps also with expansion, by contact with steam at a high temperature, although in a comparatively dry condition, during the process of grinding.

This would seem to be the logical reason of the fact that while cement manufactured from clinker chemically well balanced and thoroughly calcined would expand when submitted to the Le Chatelier test, it would not expand under the same conditions if it had been previously treated by the hydrating process.

Attempts had been made to use other materials for regulating the setting time, such as calcium chloride, sodium carbonate, &c., but as far as the author was aware these methods have not proved commercially successful. At the present time the processes employed were practically confined to watering the clinker, hydrating by means of steam during grinding, and the addition of gypsum. With these methods individually, or with a combination of same, cement could be produced having setting times suitable for all requirements.

Although the methods described made it possible to produce cement with definite setting properties, it must be remembered that the activity of the chemical process of setting was dependent upon the hygroscopic condition and temperature of the atmosphere or surrounding conditions under which concrete work was being carried out, a high temperature and a dry atmosphere tending to increase the rapidity of the set, and vice versâ.

Some tests indicating the change in the character of the setting time of cement due to temperature and atmospheric conditions, over which the manufacturer had no control, and which will always exist, were then referred to by the author, who thought their results should induce the engineer, architect, contractor, or other users of cement to supply the manufacturer with the fullest possible detail of the prevailing conditions under which the cement he purchased is likely to be used, so that the experience of those who have made this question a special study might be utilised to the full, and by the avoidance of failures thereby creating even greater confidence in the method of concrete construction, which, although developed of recent years to an enormous extent, was yet in its infancy.

Mr. Edward Holmes along with Mr. Edward M. Gibbs and Mr. Peter Marshall, has offered the Sheffield authorities to formulate a scheme for laying out the Rivelin Valley Road estate with due regard to the ultimate commercial development of the estate, and at the same time preserving the amenities of the valley and neighbourhood. The water committee have accepted the offer with thanks.

The Members of the Edinburgh Architectural Association paid a visit to Glasgow on Saturday under the leadership of the Glasgow Institute of Architects. The party drove round the city and inspected some of the more prominent buildings which have been recently erected, such as the Art Galleries, the School of Art, the Mitchell Library, the Institute of Engineers and Shipbuilders, the Clyde Trust buildings, and the new Liberal Club.

THE PRESERVATION OF IRON AND STEEL.*

(Continued from last week.)

THE electro-chemical explanation of the corrosion of iron is not complicated, and so far has been found in accordance with all the facts. Briefly stated, the explanation is as follows:—Iron has a certain solution tension, even when the iron is chemically pure and the solvent pure water. The solution tension is modified by impurities or additional substances contained in the metal and in the solvent. The effect of even the slightest segregation in the metal, or even of unequal stresses and strains in the surface, will therefore throw the surface out of equilibrium, and the solution tension will be greater at some points than at others. The points or nodes of maximum solution pressure will be electro-positive to those of minimum pressure, and a current will flow, provided the surface points are in contact through a conducting film. If the film is water or in any way moist the higher its conductivity the more rapidly iron will pass into solution in the electro-positive areas, and the faster corrosion proceeds. Positive hydrogen ions migrate to the negative areas, negative hydroxyls to the positive. By a hydrogen ion is meant a dissociated hydrogen atom carrying its equivalent static electrical charge which may be represented by the symbol $\overset{+}{H}$. The hydroxyl ion is written $\overline{OH}$. Water, which may be expressed by the symbol HOH, is made up of the dissociation products $\overset{+}{H}$ and $\overline{OH}$. An acid like hydrochloric acid (HCl) dissociates into $\overset{+}{H}$ and $\overline{Cl}$. An acid is always highly dissociated in solution, while water itself is only slightly dissociated. This explains why the presence of an acid increases the concentration of the hydrogen ions. Ionisation always takes place in every solution of an inorganic compound, and even the purest water is slightly dissociated into its constituent ions $\overset{+}{H}$ and $\overline{OH}$. The more ionised a solution is the higher its electrical conductivity and the more rapid the damage to the underlying iron. If the concentration of the hydrogen ions is sufficiently high, which is only the same as saying if the solution is sufficiently acid, the hydrogen ions wil exchange their electrostatic charges with the iron sweeping into solution, and gaseous hydrogen is seen escaping from the system. If, however, as is usual in ordinary rusting, the acidity is not high enough to produce this result, the hydrogen ions will polarise around the positive nodes, and the so-called electrical double layer of Helmholtz will be formed.† This polarisation effect resists and slows down the action. Nevertheless, although it cannot be seen, some exchange takes place and iron slowly pushes through, as is shown by the development of the blue nodes in the ferroxyl test. For every exchange of static charge between iron and hydrogen at the positive node, a corresponding negative hydroxyl ion appears at the negative node, which is shown in pink with the ferroxyl indicator. In other words, as fast as the iron sweeps into solution, the concentration of ferrous hydroxide grows, but the ferrous reaction appears in one place and the hydroxyl in another. It is now that the oxygen of the atmosphere dissolved in the solution takes up its work, the ferrous ions are oxidised to the insoluble ferric condition, which results in the precipitation of rust and the action of hydrolysis proceeds. The formation of the insoluble ferroso-ferric carbonates and hydroxides changing to the red ferric hydroxide known as rust is familiar to everyone. Even the purest iron obtainable shows the electrolytic nodes in the ferroxyl indicator, which proves that the equilibrium is so delicate that it is affected by the physical condition of the surfaces as well as by the chemical constitution of the metal. In a recent publication ‡ the author has discussed this subject at length. It was observed that in making ferroxyl mounts an indentation, scratch or wound of any kind on the surface of the steel invariably became positive to its surrounding area and thus formed a centre of corrosion. If this had occurred only upon milled specimens which carried a coat of scale or blue oxide, the explanation would be simple; but the fact is, if a freshly polished steel mirror receives a cut before immersion, the marked place comes out in blue and corrosion takes place more rapidly. It has been known

for a long time that indentations or injuries on the water surfaces of boilers become centres of corrosion and pitting. It has been shown by Walker and others that the polarity is affected by stresses and strains on the surface, and it would seem, in view of all the facts, that this condition is determined by a number of widely different causes, which may be classified as electrical, chemical and mechanical. It seems probable that the surfaces of steel which are subject to the condensation moisture of the atmosphere are always in a state of electrical strain and polarity. The ferroxyl tests show that in a large majority of cases the positive spots once formed remain positive, and so corrosion proceeds steadily to the formation of destructive pitholes.

Those who have followed the above explanation will understand the statement of the author that the rusting of iron is primarily due, not to attack by oxygen, but by hydrogen in its ionised condition. Nevertheless, the function of oxygen in carrying on the process of rusting, although a secondary one, is absolutely essential to its progress, for in the absence of oxygen rust is not formed. It is owing to these separate though co-ordinated functions of hydrogen and oxygen that the formation of rust can be inhibited by the addition to the water of certain oxidising agents, as well as by certain reducing agents, a seeming paradox that no other theory attempts to explain. The strong reducing agent pyrogallol will inhibit rusting by interference with the function of the oxygen, while such conspicuous oxidising agents as chromic acid and its soluble salts, by inducing a passive condition, interfere with the action of the hydrogen ions.

Let us now examine this theory in the light of some additional well-known facts. That the presence of acid is necessary for the continued corrosion of iron has been believed for a long time, and some authorities have even contended that carbonic acid is the sole cause of the rusting of iron. In the opinion of the author this is true only inasmuch as carbonic acid is one of the factors in the hydrolysis which produces hydrogen ions. Iron does not rust in alkaline solutions, which contain an excess of hydroxyl ions, provided the alkalinity is high enough, but in dilute alkaline solutions rusting goes on in a dangerous fashion, the tendency to pit being accentuated. This action is incompatible with the theory that free acid is necessary to induce rusting, but is explained by the electro-chemical theory. Hydrogen and hydroxyl ions can exist in a solution at the same time to a considerable extent only when they are separated or held apart by potential differences, and therefore in the rusting of iron the concentration of hydroxyl ions, or, in other words, the alkalinity, must reach a certain value before rusting is entirely prohibited. This is because, owing to the very slight dissociation of water, an excess of hydroxyl ions would be incompatible with the presence of free oxygen ions.

The Passivity of Iron.

Chromic acid and solutions of its salts inhibit corrosion of iron and steel by inducing a passive condition of the surface. This passive condition is maintained not only while the metallic surface is in contact with the solution, but also for a certain length of time after the iron is clean and dry. The passive condition, however, gradually disappears. There is a vast literature * on the subject of passivity, and the three following theories have been advanced to account for it:†—(1) A layer of oxide is formed on the surface; (2) oxygen is plated out on the surface, polarising it to the condition of an oxygen electrode; (3) the solution tension of the iron is lowered by the change of the elementary iron to the condition of its highest valency, in which state it behaves as though it were a noble metal. The first theory is untenable, and each of the other two, though based on observed facts, offers incomprehensible difficulties. It is not, however, the intention of this paper to discuss these theories, but merely to present the subject in sufficient detail to permit the consideration of the practical bearing of the general theory on the important subject of the preservation of iron.

Preservative Coatings.

The various forms of iron and steel used in the arts and industries may be, for our present purpose, conveniently classified according to the methods in most general use for their preservation.

* For the bibliography and discussion of the passive state, *see* Byers, *Journal of the American Chemical Society*, vol. xxx., Part II. p. 1718.

† H. C. Jones, *Elements of Physical Chemistry*, 1907, p. 441.

Preservative Coatings for Various Forms of Iron and Steel.

Coatings.	Forms of Iron and Steel.
Zinc, tin, copper, lead.	Roofing and sheathing of buildings; wire for telegraph, fencing, suspension cables, &c.; nails, screws, bolts, fittings, &c.; tanks, vessels, and utensils; chains for special purposes; pipes and tubes for special purposes.
Paints, varnishes, bitumens, cements, &c.	Structural iron and steel; decorative iron work, fire-escapes, railings, &c.; locomotives and cars; smoke stacks, gas and oil tanks; pipes; machinery (in part); boats and ships; boilers (on the outside); trolley poles, masts, posts, mail-boxes, &c.
Lacquers, varnishes, japans, and enamels.	Small articles, hardware utensils, implements, tools, cans, &c.
Processed after manufacture to form a skin of oxide, phosphide, or some other compound.	Structural steel, gun barrels, &c.
Usually unprotected.	Machinery (in part); tools and farming implements (in part); chains; boilers and tanks (inside); railroad rails, plates and bolts.

Taking up these preservative coatings in the order indicated, we may inquire how successful the present methods of manufacture and preservation are, and whether or not the electro-chemical explanation of corrosion is likely to be of any practical value in indicating improvements in methods of protection.

It is unnecessary to discuss at length the dissatisfaction which is so widespread among consumers of modern steel and iron, who complain that it rusts and corrodes much more rapidly than older metals made largely by hand-working in past times. The technical and scientific press is crowded with evidence of the truth of this contention.* A prominent American railway engineer, in considering the possible conservation of forest trees which would result from the substitution of steel for hardwood railroad ties, has pointed out that unless more rust-resistant metal is manufactured, such a course could not be economically followed. He further points out that the rate at which both wood and iron decay leaves little to be said in favour of either material, though reafforestation is possible, while iron ore is not capable of reproduction.

(*To be continued.*)

SOME THOUGHTS ON ENGLISH ARCHITECTURE OF TO-DAY.

By VIATOR.

THROUGH which end of the telescope should an observer glance in order to gain the best, the correct, visual grasp of architectural presentments? Should minor details be obscured, and merely broad effects noted; or, on the contrary, should the lens be used that magnifies instead of diminishing the object, thus forcing on our gaze every detail minutely? There are but few buildings that would bear such scrutiny as last implied—few buildings, whether ancient or modern, and (though no laudator temporis acti at the expense of to-day) the latter would bear such scrutiny less capably than the former.

But, irrespective of this, the just mode of observance of any building is that, dependent upon the consideration that a supercritical gazer makes no allowance for general effect, which is, at last, the most desirable effect to be obtained. Whether the principle to be observed is that "he who runs may read" or "he who stands in crowded thoroughfares should not be given too much to read," either of these suggests the desirability of broad effects as opposed to minute detail.

To an increasing extent is this consideration heeded nowadays in the British Isles; the feeling is perhaps French, though ante-dating the entente; nor need we feel any humiliation in thus borrowing from our neighbours; for England's greatness owes its origin to her Norman ancestry,

* *Railroad Age Gazette*, 1908, vol. xlv. p. 24.

consequently French influence worked upon by insular requirements is without reproach Broad effects, however, do not connote a mask of ugliness; and too often the latter is suggested, whence is obtained the New Art, a deplorable phase, whose passing is not yet.

These few jottings are not concerned with holding up to condemnation or to commendation any individuals or buildings, the object being to display motifs rather than motif-producers. Nor need anything more than this passing notice of ancient art be set down here. The glories of the past are indeed universal heirlooms, gaining in interest and in reverential consideration with the flight of time. The works of to-day, on the other hand, are properly open to criticism, as by this means improvement is possible, and the continuation of exercises and experiments, which can but travesty art, may be thus discouraged.

If we are correct in saying that a building should provide broad effects, this implies that everything in the design and grouping must have the relative importance that it may properly demand—that and no more. A further deduction is that "art for its own sake" is to have a different interpretation from that advocated by extremists, whom we hostilely designate "purists." The expression of art is first and last for the satisfaction of the capable beholder in general, and not of the producer in particular; the over-elaboration observable in some buildings could only be justified if the first-personal equation were admissible. Mutatis mutandis, the same equation would alone justify the cowhouse architecture of to-day.

Dealing with this vast London merely, are there two dozen, are there even a dozen, buildings of the last century that would incontestably rank as fine examples of architecture in the eye of the capable observer? And yet if we set aside a too extremely stringent standard, if we apply but the small lens of the telescope, if we will satisfy ourselves with general effect instead of absorbing inconsiderable details, we shall experience greater and at the same time rational satisfaction from much of our modern architecture, and we shall be cognisant of signs of improvement, giving golden hopes for the future.

The agreement between internal disposition and external expression is becoming progressively marked in these days, even when it entails (what has been termed) an ametrical elevation; such honesty is truly the best policy, the virtue of it bringing in its train the due reward in the increased interest and vigour appertaining to the appearance of a building so treated. It is not many years since such treatment would have been regarded with horror. Let it be granted that the struggle between revealment and concealment is long-contested and that the latter dies hard, but the dragon will finally be slain.

This, then, is one of the broad effects that should be characterised for the benefit of observers, and another is the abolition of meaningless and superabundant adornment of surfaces. The eye demands that these shall be broad and restful, and that groupings shall be well defined and well disposed. The desideratum is for ornament that is characteristic of the building, and for such ornament only; or, if there be no special character, then the decoration should be at least restful and of good repute.

In this respect, too, the signs of the times are on the whole healthy, though some terrible warnings—or shall we venture to say backslidings?—meet the eye in some quite modern buildings. That sensitive organ seeks a resting-place in such instances as hopelessly as the dove on its first flight from the Ark. Mostly it is modern Gothic that so offends, a fact much to be regretted by true lovers of the vernacular, as the numerous examples of Gothic restraint evidence the superiority of the latter. It is not the application of the small lens of the telescope that will serve to obliterate such over-elaborated designs; nothing short of shutting the eyes can remove the effect of restlessness thus obtruded upon the notice of the passer-by. In the desire, however, to obtain breadth and restraint, some modern work exhibits all the defects of the New Art, which resembles nothing on the earth beneath the heavens, and, it may be fervently hoped, resembles nothing in the heavens above. Broad effects and limitless effects are distinguishable; we want the former and should shun the latter. It is a question of massing, not only in regard to constructive materials, but respecting colour also. We see chessboard treatment here, and there we are confronted and affronted by the spotted fever.

When all is said about the British "sheep" and the proletariat, it is however true that well considered buildings will gain the suffrages of the crowd in its moments of self-forgetfulness; and even though, maybe, unwitting of the basis of its approval, such approval will be far more often just than ignoble. Dr. Samuel Johnson rightly threw scorn on the saying, "He who drives fat oxen must himself be fat," and for all ideas of this nature similar scorn is appropriate; lovers of good design are not necessarily, nor perhaps principally, confined to the ranks of those who can produce it.

The rapprochement between the arts and crafts is in every way to be commended as long as a spirit of selflessness and subordination rules, exhibiting a desire to promote the best results, regardless of the relative prominence or middle distance of the collaborators. Perhaps adherence to this principle will come most easily to the architect, whose portion of the work, in the vast majority of cases, will necessarily hold first rank. But from this very fact it is evident that the architect is thus in the best position to foster to the utmost the friendly collaboration of the other arts and of the crafts. To the unbiassed observer there seems no more reason why architectural qualities should not be applied to engineering structures, than for the engineer to collaborate with the architect, and the latter is found ever ready to subordinate himself in the work on those public memorials where the sculptor takes first rank. Such being the case, the architect should be able to reckon on the cordial co-operation of others, whether artsman or craftsman.

It is a hopeful sign in present-day England that we have set aside the restless searching after a new style; the period is not far to seek when such searching was in evidence, but now the attempt to create a style has given place to the healthier idea of grafting on to existing types the motifs naturally arising from modern requirements. To reject ancient and established styles, whose merits are apparent, would be childish; but side by side with them, or, as just suggested, by adapting their underlying characteristics, a new style or many new styles may arise by degrees. Evolution is always to be preferred to revolution.

DISCONNECTING TRAPS.

AT a meeting of the Sanitary Inspectors' Association held recently at Bath, Mr. J. T. Moss-Flower, C.E., F.R.S.I., opened a discussion on the disconnecting trap in drains. He stated:—

That it is most desirable that there should be fixed on the line of drain between the house and the sewer an intercepting trap, so as to keep the sewer air as far from the house as possible.

That the fixing in a proper manner of an intercepting trap of suitable size, shape and form affords an effectual barrier to the passage of any germ of disease or sewer air from the sewer to the house.

That he had examined the drainage of houses where there was no intercepting trap between the house and the sewer, so that the sewer air was enabled to pass freely to the inside of the house through defective drains and sanitary fittings, and that this was alleged by medical attendants to have been the indirect, if not the direct, cause of the specific form of disease from which the inmates were suffering.

That he had examined the drainage and sanitary arrangements of a large number of houses where in each case there was an intercepting trap on the line of drain, and he gave particulars of the defects discovered, such as periodical syphoning of traps of water-closets, which allowed drain air to enter the house, and which, but for the intercepting trap, would have given a free and uninterrupted passage to the house for the sewer air.

That, in the absence of a trap on the line of drain, any germs of disease which may find their way into the sewer from an infected stool or otherwise may pass up the house drain of a neighbouring house and into the house through one of the numerous defects that may exist in the drains and general sanitary arrangements and be imbibed by the inmates.

That he had never known any evils to arise in connection with the numerous systems of drainage constructed by him during the last twenty years in connection with which intercepting traps were fixed, and that of the large number of intercepting traps fixed by him he has only known of one becoming choked, and that was due to the carelessness of workmen in allowing some cement to fall into the well of the trap.

That the abolition of the intercepting trap would prove very disastrous, and that it would not be advisable in any case unless the public sewers were constructed, covered,

Digitized by Google

cleansed, ventilated and kept at all times so as not to be a nuisance or injurious to health, and unless the house drainage and general sanitary arrangements of all houses draining into the public sewer were also constructed and maintained constantly in a perfectly sound state; but since it is not possible to insure this, the intercepting trap is the best safeguard to the health of the inmates of houses.

That where complaints have been made against the use of the intercepting trap they arise from one or more of the following defects:—(*a*) The trap is too large or too small; in the former case difficult to flush, and in the latter liable to choke. (*b*) The trap is of improper shape and form, offering obstacles to the flushing out of its contents. (*c*) The invert of the outlet of the trap is on a level with, or above the level of, the inlet, in the latter case causing the sewage to pond back in the drain. (*d*) Carelessness of workmen in fixing the trap out of level, either tipping it towards the outlet, thereby breaking or reducing the water seal, or tipping it towards the house and making the outlet higher than the inlet, thus causing the sewage to pond back in the drain, as in (*c*); also in not clearing the cement from the inside of the pipes at the joints, &c. (*e*) By fixing the traps, in cases where there are no special automatic flushing tanks, so far from the house that all ordinary flushes of water have so spread out along the invert of the drain as to have no flushing power by the time they reach the trap. (*f*) By giving too little fall to the house drains to which the traps are connected, causing the traps to choke. (*g*) In the case of disconnecting chambers by fixing intercepting traps with inspection eyes leading to sewer, which inspection eyes are capped by a plain stoneware disc that can be easily blown out by pressure of air or otherwise, these stoppers under normal conditions being seldom tight and allowing sewer air to enter the drain.

That the foregoing defects can be avoided if proper care be observed, and that by carefully selecting the trap and taking due care in fixing and in selecting the position no evils need arise, and that as regards the inspection eye on the outlet end of manholes the disc closing the opening should be so arranged that it cannot be removed by sewer men thrusting the rods up the house drains from the sewer, or by pressure caused by sewage or air, and yet so that it could, if necessary, be quickly opened from the ground level without entering the manhole.

That he has made detailed examinations of a large number of premises where one or another of such diseases as typhoid fever, diphtheria, blood-poisoning, &c., has broken out, and in every case he has found serious defects which admitted either drain or sewer air to the house, to which defects the medical attendant has attributed the disease.

That in other cases, particularly in boarding schools, where there has been no specific form of disease that could be diagnosed by the medical attendant, but a general low condition of health has been prevalent among the inmates, he has found the sanitary arrangements most defective.

That in his opinion it would be necessary, in the event of the intercepting trap being abolished:—(*a*) To insist on a very high standard of workmanship and material in connection with the construction of house drains and sanitary arrangements generally; (*b*) to arrange for a much better system of supervising the carrying out of such work; (*c*) to arrange for periodical tests and examinations at much more frequent intervals than are usual at present to make sure of the pipes and fittings being maintained tight and sound and proof against allowing drain or sewer air to pass into the house; (*d*) to discontinue the practice of providing low-level inlet ventilators to drains, as now provided under most local authorities' by-laws, and to arrange for all ventilating openings to be carried to a point well above the roof and away from all windows. (This plan, it was pointed out, is desirable even where there is an intercepting trap, but it would be much more so were the interceptor abolished.)

That his observations, extending over a period of many years, make it clear to him that the low condition of health shown by the inmates of houses where drain or sewer air has access to the house is often to be attributable to the imbibation of drain or sewer air.

Mr. Moss-Flower then went on to speak of the ventilation of sewers and drains, and said that the ventilation of sewers and drains is absolutely necessary, and in the case of house drains (*a*) to prevent the air in any part of the drains or pipes from being compressed to such an extent (by the discharge into the drains or pipes of water) as would endanger loss by momentum of the water seal of traps; (*b*) to prevent stagnation of the air in the drain, so that if there were defects in the drains or fittings the air passing into the house because of them would not be so harmful or obnoxious as would be the case where there is no ventilation.

That in the case of drains there should be not less than two ventilating openings as far apart as possible, and that low-level inlet openings, now often fixed in basement areas and such places, should not be permitted, a low-level inlet only being allowed where it can be fixed a long way from the house, and where the discharges from it cannot be a danger to the occupants of the house or anyone else.

That since one of the objects aimed at by those who advocate the abolition of the intercepting trap is the ventilation of the sewer by means of the soil pipe continuation to the roof, the point of outlet for the ventilating pipe would have to be selected with great care, and that in many instances it would be most difficult to find a point which would be sufficiently far from windows and other openings into the house to avoid a nuisance and danger to the health of the inmates.

That the ventilating pipes from the drains of one house should not be so arranged that, although the outlets may be clear of all the openings into the house they serve, they may be a danger to the inmates of an adjoining house, as is very often found to be the case.

That, as regards sewers, his experience teaches him that ventilating openings at the ground level are the most undesirable and give rise at least to serious nuisances.

That, generally speaking, tall ventilating shafts and columns fixed in carefully selected positions are the most desirable, and that in places where columns must be erected in exposed positions and close to frequented places and houses, then one of the forms of lamps for cremating the emanations is desirable.

That if the size and form of sewers are properly apportioned to the work they have to do, and they be constructed of non-absorbent and otherwise proper materials, and be laid with self-cleansing velocities, and be regularly flushed and have ventilating shafts fixed at proper and convenient places so as to prevent undue pressure from rise of temperature, rapid increase in volume of flow, &c., and manufacturers' refuse, which should be properly treated before being discharged into sewers, and steam and hot liquids above a certain temperature be excluded from the sewer, much will have been done to reduce the nuisance caused by the emanation from sewers.

LONDON MUNICIPAL HEAT SUPPLY.

By ALFRED E. WHEELER, C.E.

(*Continued from last week.*)

IN order to make my proposals as clear as possible, I will classify them under the following four heads:—(1) Quantity of heat. (2) Generation of heat. (3) System of distribution. (4) Payment for supplies.

(1) *Quantity of Heat.*

To arrive at the amount of heat which is likely to be required, and which must be provided for, is necessarily no simple matter, and sound judgment, rather than strictly theoretical figures, will be found of the greatest assistance. First it will materially assist if we consider the purposes for which heat will be required, and in this connection I take the opportunity of inserting a reminder that as smoke abatement is the object of the scheme, the coal fire may be considered as out of the question, therefore a quantity of heat sufficient to entirely supersede the open fire must be provided for.

The purposes for which heat is required are generally three in number:—(1) Heating buildings and apartments. (2) Preparing food for consumption. (3) Heating water for domestic uses. In addition to these some consumers may require steam for various purposes.

Either of these objects could be accomplished by means of gas ranges and fires, but there is very little doubt that from the standpoint of cost, which is the factor which appeals most strongly to the majority of the community, Nos. 1 and 3 will be most suitably accomplished by the public supply, as the comparison made in a later section (payment for supplies) shows the cost of heat by supply mains to be infinitely less than that furnished by any other means. We will therefore assume that the great bulk of the heat available will be supplied for purposes Nos. 1 and 3, that cooking will be accomplished by gas ranges, and that small steam supplies may be generated by either means.

The estimate of the population of the County of London, made by the Registrar-General in June, 1906, was 4,721,216,

Digitized by Google

and as it is usual with all calculations for public supply to make allowance on a *per capita* basis, I propose to make my calculations for our heat supply on the same lines, although the method is not an ideal one.

As an example of the failure to meet the case in a representative way, the two instances of the boroughs of Kensington and Stepney will clearly illustrate.

The population of the former borough is generally of a superior class to that of the latter, and accustomed to a higher standard of domestic comfort. We should, therefore, quite naturally expect a greater heat demand from Kensington than from Stepney in proportion to the population, yet by our *per capita* method of computation we are confronted with this paradox:—Stepney has 1,700 head of population per acre; whilst Kensington has but 805 head, rather less than half; although for reasons just stated we would expect a greater demand from Kensington than from Stepney, we are actually allowing a *reduced* supply per unit of area.

It would therefore seem to be more accurate to allow heat in proportion to the area or to the rateable value of the houses and buildings. However, for the present purposes, the population method will serve.

It has been estimated that the coal consumption per head for the United Kingdom averages 1.25 tons per annum, which at a heat value of 14,500 B.T.U. per lb. gives a heat consumption of 6,200 B.T.U. per head per hour of an eighteen-hour day.

As previously pointed out, about 58 per cent. of the total heat of the coal burnt in most open grates is lost by imperfect combustion or up the chimney, therefore the net value of the heat per head per hour would work out at about 2,600 B.T.U. To be quite upon the safe side, I propose to calculate on the basis of 5,000 B.T.U. per head per hour, which gives a maximum hourly requirement of some 23,528 millions of B.T.U., supposing that each household were drawing upon the heat supply the maximum amount simultaneously.

For a large portion of the year, during the warmer periods, the London households will require but little heat for warming purposes and a comparatively small amount for hot water supplies. At all times the demand is likely to fluctuate considerably, therefore we are faced by the difficulty of providing for a heat supply which may vary between limits as wide as 50 or more per cent. above or below normal, and which might conceivably involve a large capital charge and interest upon plant lying idle for a considerable portion of the year, a condition to be avoided as far as possible. Here it is, therefore, that our judgment will avail us most in determining what proportion of the total heat we should be prepared with, making due allowance for all possible fluctuations in demand.

As will be presently shown, all heat for whatever purpose would be drawn from the same mains, therefore the variations in demand will no doubt go far to equalise each other. It should also be pointed out that although the figures given represent a capacity sufficient to supply the entire population, a not inconsiderable share of the duty would necessarily fall upon the gas and electric supply companies.

Taking all these various factors into consideration, and duly considering the possibilities of an increase in the number of consumers for which it is necessary to make provision, it is suggested that a plant equal to an hourly duty of 66 per cent. of the total should easily meet all our requirements: the hourly output will therefore be 15,672 millions of B. T. U.

These figures, of course, apply only to the requirements of the residential suburbs of London outside the City. To deal with the latter area is a somewhat different matter, the population being largely a day population only. As a way out of the difficulty, it is proposed to provide for the City a supply in the same ratio to its area as that of other thickly populated districts, an arbitrary figure of 338 millions of B.T.U. per hour being suggested.

(2) *Generation of Heat.*

Before proceeding to a description of the method of generating the heat a brief description of the system by which the heat would be supplied will perhaps facilitate a better understanding of the methods of generation and dissemination. The heat would be generated in specially constructed water tube boilers, provided with forced draught and mechanically fired. Each boiler would have about 5,200 square feet of heating surface and 57.65 square feet of grate surface, and be arranged to burn smokelessly 30 lbs. of coal per square foot of grate surface per hour, with a thermal efficiency of at least 72 per cent. The heat would be distributed by means of water heated to 350 degrees Fahr. under 250 lbs. per square inch pressure, pumped through the supply mains, and returning to the boilers at 250 degrees Fahr., each 1 lb. of water thus conveying 100 B.T.U. The heat would be supplied to the consumers by the indirect method, that is, each consumer would be provided with units of heating surface of a standard heating duty which would be connected to the supply mains with a meter in circuit, the heating surface being fixed in a tank or other enclosure, and surrounded by water for the purpose of removing the heat; the enclosure or tank taking the place of the boiler or calorifier well known to all heating engineers. It will be seen that this system possesses among many others five distinct advantages, viz.:—

1. The water of circulation being constantly re-used, all accumulation of scale is thereby obviated in the mains, and on the interior of the heating surfaces of the boilers, the importance of which cannot be exaggerated, when it is remembered that so much depends upon the tubes of the boilers being kept free from scale, both from the standpoint of expense in cleaning and tube replacement, and also the loss of heat efficiency.

2. This method of circulating the water merely requires the replacement of 100 B.T.U. per 1 lb. of water per hour. If on the other hand hot water were supplied direct to consumers at, say, 200 degrees Fahr., an additional 50 B.T.U. per lb. would need to be transmitted at an increase in fuel cost by probably nearly 50 per cent.

3. To deliver heated water direct would involve a large annual charge for water at the central station, the suggested method avoiding such a charge.

4. The system of generating heat under pressure will permit an increase of temperature by 50 degrees if necessary (while still maintaining the same temperature head), to meet any suddenly increased demand for heat.

5. With a single pair of mains such a system would enable all heat requirements to be met, and while being principally directed to heating water, the heat could also be applied to the generation of small supplies of steam. Further, the suggested method obviates the necessity for separate mains for heating, hot water supply purposes and for steam supplies.

(*To be continued.*)

ART EXHIBITIONS.

THE ninety-sixth exhibition at the French Gallery is devoted to four acknowledged masters of painting; they are Israels, Mathew Maris, Harpignies and Lhermite. Their names will be familiar to everyone who has sufficient interest to pay a visit to the single room at 120 Pall Mall, S.W. But it is almost a certainty that very few of the ordinary visitors will possess anything but the haziest ideas as to the positions occupied by these four great masters and their relationship to contemporary art. If this is the case it would have been a great help had some introductory notes been inserted in the catalogue, thereby rendering more intelligent the admiration and interest which cannot fail to be excited by these sixty works. Mathew Maris is an artist of the strongest individuality, as is suggested by the portrait of himself. Though he has passed the three score years and ten, it is believed that the total number of works by him in existence is less than seventy, and of these seventeen are now on view in the French Gallery. They cover a considerable period of years, and are of sufficient variety to ensure that there will be something attractive for everybody. Only the initiated can appreciate "The Christening," a pastel; but such a picture as "The Young Cook" or "The Prince and Princess" will appeal to all. Each of the pictures shows in a greater or less degree the poetic and fanciful sympathies of Maris. There seems to be one exception to this in No. 11, "On the Beach," where the painter apparently found himself overpowered by the commonplace. Joseph Israels seems to be haunted by thoughts of tragedy, from which he can rarely escape. The place d'honneur of the gallery is accorded to his large picture, "The Drowned Fisherman"—a melancholy procession headed by a young woman with two small children; she is followed by two sailors carrying the gruesome body, and a line of men and women. The storm has almost passed and left the water innocently calm, though its severity is unmistakably shown in the wrecked fishing-smack as well as in the sky. The same feeling of sadness must have inspired the "Sheltering from the Storm," where a helpless shepherd and a small flock are standing assaulted by a pitiless storm. "Honoured Old Age" is a stern portrayal of an old peasant woman trying to warm herself over a small fire, though there is here nothing to wring the heart, for the dame assuredly counts herself happy. The landscapes by H. Harpignies and

Digitized by Google

L. Lhermite make an interesting comparison. It is difficult to realise that M. Harpignies painted "Sunset on the Banks of the Ain" at the age of eighty-five. The artist cannot have lost anything with the years to have achieved such a chef-d'œuvre. Unlike many of his other pictures, the atmosphere is full of iridiscence. M. Lhermite is represented by several country scenes. Nos. 44 and 45 might be the same river viewed from opposite banks, yet there is no suggestion of repetition. The whole collection is a memorable one, and it is believed, and it is to be hoped, that it may be exhibited in some provincial cities.

There are many who are reduced by the poems of Robert Browning into a state of bewilderment. It would be incorrect to say that a key is now offered by which their inner meaning may be read; but we do say that a new interpreter has arisen in Miss E. Fortescue-Brickdale, A.R.W.S., whose illustrations have been published with certain of the poems by Messrs. Chatto & Windus. The original of these with a few others are now on exhibition at the Dowdeswell Galleries. No doubt the translation is a very free one, and that Miss Fortescue-Brickdale drew more from her own imagination than she did from the poet. Yet this was almost inevitable in the case of Browning, whose genius was too quick to be content with expanding or developing one fixed idea. The water-colours show at any rate what a wealth of fancy may be drawn out of the poems. The artist has come to her task with the assurance of past successes, and has thereby gained in freedom and boldness. The pictures are gay with colour from a generous palette, and the subjects have all that picturesqueness and charm that might be expected from a lady artist with a love for poetry. On the few occasions when she permits herself to leave the realms of fancy there seems a certain lack of pleasure. An exception is, "But God has a few of us whom He whispers in the ear." The girl carrying the pail is no doubt a most conscientious maid-of-all-work, but her mind evidently travels on a plane that few can hope to reach. The pictures are charming, none the less so because their meaning is (unlike Browning's) not difficult to decipher.

NOTABILIA.

THE photographic and literary snapshots given in the *Badminton Magazine* for June, under the title of "Motoring in Touraine," may be recommended to anyone contemplating a tour in France, whether on foot, awheel, in a motor, or by train. Touraine offers splendid roads, a kindly and unspoilt population, some unrivalled and well-known châteaux (which include Chenonceaux, Amboise and Azay-le-Rideau), and many historically interesting towns. The letterpress has been written fluently and enthusiastically. We might perhaps remark, at the risk of seeming hypercritical, that Chenonceaux should not be described as "du vrai Gothique," and that the corners of Azay-le-Rideau are not marked by square turrets, but by round towers with conical roofs.

The *Antiquary* gives an account of "Some recent discoveries at Burgh Castle" (near Great Yarmouth), in which is recorded the addition of more interesting specimens of Romano-British pottery than in the past to the examples found at Burgh. "A graphic method of finding the point of sunrise on Midsummer Day," by C. W. Dymond, F.S.A., should be suggestive and useful, not only to those interested in prehistoric monuments, but to students of the orientation of our Mediæval churches.

OUR CONTEMPORARIES FROM OVER-SEAS.

THE *Architectural Record* commences with an article for the client on "Selecting the Suburban Home Site," with the keynote of which we agree. "A building site is, or should be so considered, an object of art—a jewel in the rough;" hence the desirability of the prospective home-builder being guided in the selection of the site by the artist who is to design the house. "A Monumental Work of Landscape Architecture" is an account of the metropolitan park system of Boston. "Architecture in the United States," by Claude Bragdon, is a critical history of the earlier phase and of the birth of taste in American architecture. An illustrated account of the châteaux of le Lude and de Jarzé is an interesting study.

Moderne Bauformen as usual deals wholly with examples of the "new art" as at present being practised in Germany, where they have got away from the irresponsible and uneasy meanderings of curved lines that characterised the first stages of l'art nouveau. "New art" in Germany is now restrained and dignified, marked, if anything, by an almost affected simplicity. The examples given in the present number are mostly from the designs of Professor Alfred Grenander, of Berlin; Herr Rudolf Bitzan, of Dresden; and the trading firm of furniture makers, Anton Pössenbacher, of Munich. The applicability of "new art" to many uses, from railway stations to churches, is illustrated in several instances by coloured views of quite harmonious schemes of interior decoration.

Het Huis has an interesting article on the old-world village of Rijnsburg, between Leyden and Katwijk, with illustrations from photographs and old engravings of its eighteenth-century work and ruined abbey. A view of the house occupied by Spinoza is of literary interest. A modern house in Rotterdam, of which Mr. D. F. Tersteeg is architect, is illustrated by plans and photographs. There are some quite refreshing designs for cottage pianos, simply and logically treated.

The *Engineering Record* gives a description, with illustrations, of "The building and equipment of the Keewatin flour-mill," which has a milling capacity of 5,000 bushels per day and possesses a grain storage elevator with a capacity of 750,000 bushels.

GENERAL.

The Shropshire Archæological Society held their annual meeting on Saturday. The report of the Council stated that the restoration of the tower of the Abbey Church, Shrewsbury, had been brought to a successful conclusion. Attention had been lately called to the interesting Norman chapel, now in ruins, situate at Malinslee. It possessed many interesting features, and on more than one occasion the Society had assisted in its protection. There was now an idea on the part of the parochial authorities to completely restore it, so that it might be used for Divine worship.

Messrs. Sharman & Archer, of Wellingborough, have been appointed by the Northants education committee architects for the proposed county girls' school at Wellingborough. The secondary school buildings sub-committee reported that they had authorised the secretary to inspect, with the architects, any six modern girls' secondary schools which he thought it desirable to see.

The New Church of St. Alban's, Bournemouth, was dedicated by the Bishop of Winchester on Thursday, June 3. The church, which has been built at a cost of 12,000*l.*, occupies a favourable site on the Charminster Road. There is a considerable fall in the level of the site from west to east, of which the architect has taken advantage by placing large crypt vestries under the chancel and chapel, and connecting same with the church by a broad flight of stone steps. Although the cost of building has necessarily been increased by the requirements of the site, yet the external architectural effect of the east end thus raised some 17 feet higher from the ground level is greatly enhanced, and this added to the fact that the vestries obtained are large and spacious enough to be used for parochial purposes fully compensates for the additional outlay involved. The plan of the church consists of a nave 93 feet 6 inches in length by 30 feet 6 inches in width, with lofty double transept north and south. A lofty arch carried up nearly to the whole height of the church divides the nave and chancel, the latter being 40 feet in length by 27 feet 6 inches in breadth. Passages for returning communicants are placed on either side, divided from the choir by oak screens, with galleries over on the north and south sides for musicians and the organ respectively. An apsidal-ended chapel is thrown out east of the north transept, and a sacristy is placed on the south side of the chancel. A baptistery is placed centrally between two western porches, and a tower and spire (not yet completed) will occupy a position at the western junction of the north transept and aisle. There is accommodation for 812 adults and a choir of forty-two, with musicians' gallery in addition. The external facing is of Purbeck rock-faced stone relieved by bands and dressings of Monk's Park stone. The interior is faced with red and yellow stock bricks, relieved with Corsham Down stone bands and dressings. The whole of the floor of the body of the church is of Goddard's wood block. The chancel is paved with various coloured marbles, and the chapel and baptistery with Rust's mosaic. The heating is by low pressure hot water supplied by Messrs. C. P. Kinnell & Co. The church is lighted by electricity, the wiring being carried out by Messrs. Bryant & Co., of Bournemouth. The whole work has been excellently carried out by Messrs. Bowman & Sons, builders, of Stamford, from the designs and under the supervision of Mr. G. H. Fellowes Prynne, F.R.I.B.A., architect, of Westminster, S.W.

The Architect.

THE WEEK.

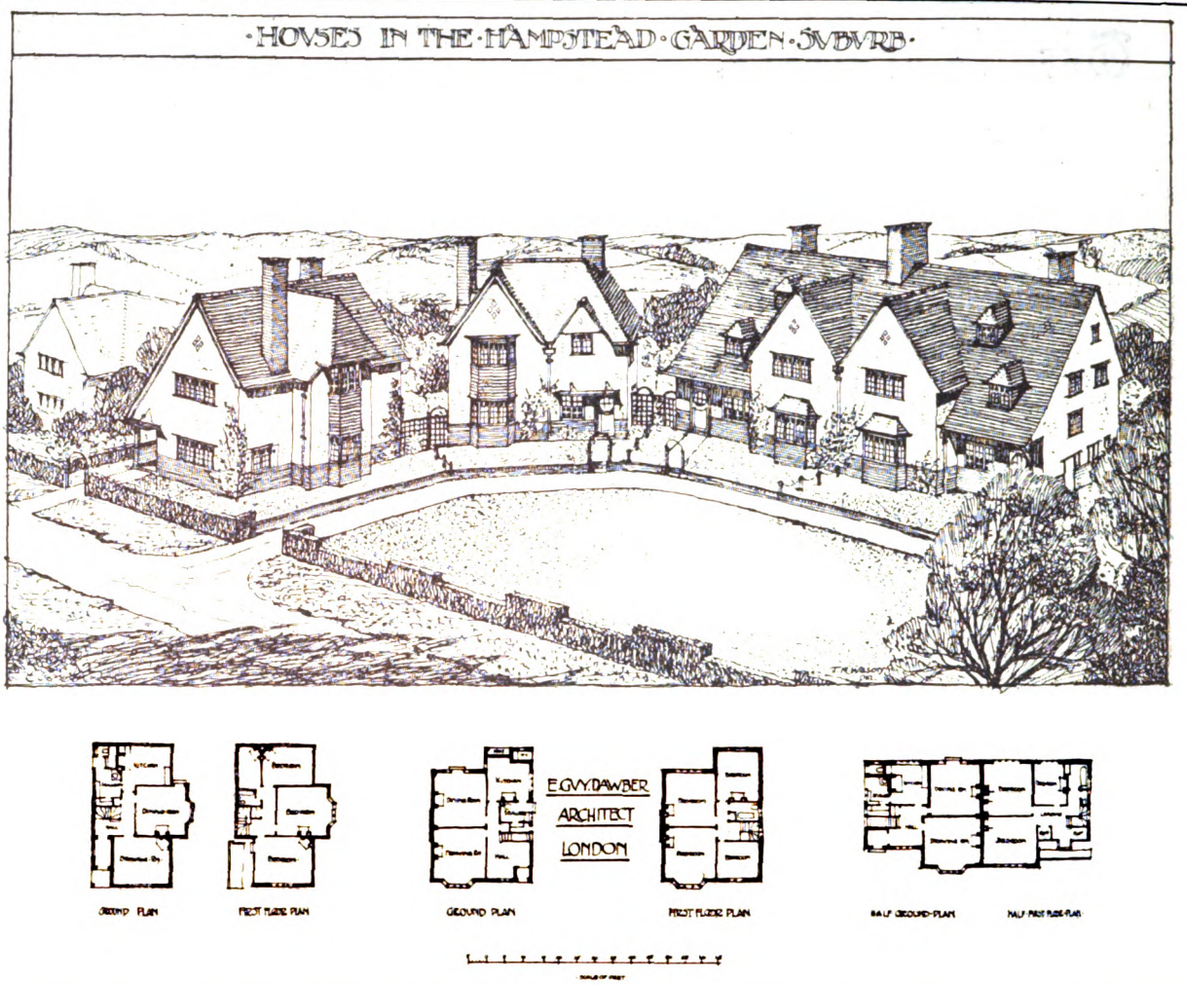
Business meetings at the Royal Institute are usually amusing, but show a dangerous tendency to descend from the plane of comedy to that of farce, and certainly are rapidly demolishing all grounds of justification for the claim made by some members of the Council of respect for the high business ability with which the affairs of the Institute are managed by them. The proceedings on Monday last show that the business ability of the Council does not extend to the management of a general meeting. Amendments are allowed to be piled on top of amendments, even to the extent of considering those to propositions that are not before the meeting; members of Council, as well as ordinary members, speak two, three, and even four times on the same question, and discuss previous amendments when subsequent ones have been proposed; the Chairman and his colleagues on the Council hold whispered consultations whilst the Secretary starts counting votes on a proposition that has not been put by the Chairman; the Chairman declares a resolution carried, and then, after elaborate and prolonged calculations to ascertain how many votes are two-thirds of twenty-six, finds that it has not been, and puts it again, when the opponents are so flustered that it is legally carried.

Amidst such an imbroglio and muddle it is not surprising that the consideration of the new by-laws proceeds slowly, the total result of last Monday's meeting being the adoption of three non-contentious by-laws without discussion, and the passing of one other with an amendment after much talk and floundering amongst propositions and divisions. The amendment which took up so much time and was finally adopted was one extending the principle of a limited term of office proposed by the Council for Presidents, Vice-Presidents, and Honorary Secretaries to ordinary members of Council also, the precise method determined being that one-sixth of these ordinary members, seniors in service, should be ineligible for re-election for two years. The meeting was not at all influenced by the forebodings of present members of the Council as to the terrible disasters that would arise from the enforcement of such a regulation, nor was it to be diverted from its wishes by the naïve request that the matter might be referred back to the by-laws committee, after being told that the result of prolonged and very careful consideration of the subject at many meetings of the committee and two or three meetings of the Council was that the President's forecast of the adoption of the principle of limitation was ignored.

It is not surprising that London is following the lead of Lancashire, and we expected that such an event would happen. Lancashire has set the fashion—a bad one—of limiting competitions by geographical terms. Now the Council of the Metropolitan Borough of Deptford, in their advertisement of a competition for a new library at New Cross, limit the same to "architects practising in the City or County of London." Though the principle is one with which we do not agree, it is only right that if it is adopted by the provinces it should be followed by the metropolis. The guinea deposit for a view of the conditions is to be refunded if the particulars are returned within twenty-one days.

Public opinion in Paris is reflected in the Municipal Council, and thus the action of the latter in insisting on the observance of the regulations respecting the height and architectural design of buildings is generally approved. The tendency towards the erection of sky-scrapers is to be nipped in the bud by the abrogation of the decree of 1902, permitting the erection of buildings 100 feet high. The erection of abnormally lofty buildings is but the speculator's dodge for getting the better of his landlord and recouping himself with an enhanced profit on an inflated ground rent. When there is a limit to the height to which a building may be carried, there is also a limit to the ground rent on which it can expect to make a profit and therefore to the unearned increment of the ground owner. It is surely right that the general welfare of the public should not be sacrificed to the profits of the lucky owner of the land, and the Parisians are shrewd enough to see that both the beauty of their city and the health of its inhabitants will suffer by the advent of the *gratte ciel*.

As the *Times* rightly points out, one of the principal elements of the charm of Mont Saint-Michel is that it is an island, at any rate practically so at high-water and sufficiently for æsthetic effect despite the causeway made in 1880. The causeway has undoubtedly rendered easier the reclamation of land in the shallow bay and accelerated its silting up. It is now proposed to remove for 1,000 metres the embankment on which the causeway runs and to carry the latter for this distance on a stockade of piles. Further, the reclamation of land is proposed to be forbidden within 1,000 metres of the island, which with these remedial measures may still retain its character, to which so much of its charm is due, of a sea-girt isle.



We are glad to learn that the Freemasons of the Province of Lancashire have succeeded in raising the sum of 10,000*l*., to which they pledged themselves for the erection of the chapter-house of the new Liverpool Cathedral as a memorial to the late Earl of Lathom, their P.G.M. The chapter-house, for which Mr. Gilbert Scott has prepared a fresh design, is to be a distinct and octagonal building on the north side of the cathedral, and will be commenced in the immediate future.

The Norfolk and Norwich Archæological Society have done well to hold their annual meeting this year at East Dereham rather than in the city of Norwich, as they have usually done. Such decentralisation widens the area of interest and leads many to join a society which thus shows that its field is the county rather than the county town. In this way many matters are brought to the notice of the Association which otherwise would be perchance known only locally, and in archæology and antiquarianism a wide dissemination of knowledge, particularly when relating to new discoveries, is of the highest importance, as it is only by collating separate and scattered data that any generalisation of historical science is possible.

Faculty law is a fearsome thing and receives illustration from the case of the parish church of St. Anne and St. Agnes with St. John Zachary, Gresham Street, in the City of London. Here some adjoining owners had raised their buildings and rearranged their lights overlooking the churchyard, and although the arrangements and compensations were approved by all concerned, the rector, the churchwardens, the building owners, the Ecclesiastical Commissioners, and the Bishop of London, as patron of the benefice, a faculty was necessary to enable the various parties to enter into a mutually satisfactory agreement.

The excavations at Caersws by Professor Bosanquet, F.S.A., on behalf of the Liverpool Committee of Excavations and Research in Wales and the Marches are proceeding satisfactorily, and the clay mound that held the feet of the supports of the watchman's tower has been discovered. The main road to the prætorium has been uncovered, and it is expected that the plan of this, the headquarters of the largest Roman camp in Wales, will in a few days be recognisable.

GREEK ARCHITECTURE.

FEW architectural students have hitherto given much attention in their study of Greek architecture to the methods of construction in use among the Greeks, save to that of the marble-built temples of the Periclean age. We are glad therefore to find in the latest addition to the list of books on Greek architecture for the serious student * that considerable attention is given to the details of construction, not only in stone and marble, but in wood, brick, terra-cotta, concrete, stucco and metals.

It will be a revelation to many architectural students to be informed that the Greek method of constructing floors was by the use of a system of girders which supported the joists, on which were laid the boards; that half-timber construction was in common use, and that piles were not infrequently employed, elder, elm and oak being considered the most suitable timbers for this purpose. In brickwork the value of bond by means of stretchers and headers was well recognised, and although our knowledge is not precise it would appear that the arrangement of headers and stretchers in alternate courses or English bond was most general. In connection with the question of bond, Professor MARQUAND is not quite correct in stating that "in modern brickwork it is customary in England and the United States to lay a course of headers above every five or six, or even ten courses of stretchers." It may be customary in the States, but in England such a method is known as "garden wall bond," and is seldom employed except for the purpose indicated by the designation. Bond timber was a device that according to Professor MARQUAND dates back as far as the second prehistoric settlement at Troy, about 2200 B.C. Though the bricks used by the Greeks were for the most part merely sun dried, the making of baked or burnt brick was not unknown to them, and the many examples left of terra-cotta work prove that its manufacture was well understood even to such technical details as the lightening and cradling of the back, and the use of slip for facing.

Professor MARQUAND's book is logically arranged on a synthetic system, commencing with the details of construction, into which, as may be gathered from instances that we have already quoted, he goes very thoroughly and minutely. Having thus formed the nucleus he proceeds to build up around it by explaining the architectural forms in which the methods of construction were employed. Under the term "architectural forms," he considers the varied treatment adopted by the Greeks in foundations, walls, antæ, doors and windows, pillars, columns and piers, entablatures, ceilings and roofs. In the description of all these remarkable thoroughness is shown, and the student has lucidly presented to him the evolution of, as well as the variations from, the prevalent type in each instance. The account, for example, of the Ionic capital, and the light that is thrown upon its development by a study of archaic examples is most informing. For this information and much of a similar character the British and American student has in the past been obliged to refer almost entirely to the works of German writers, a rather hopeless source of information to most English-speaking architectural students.

The important subject, in Greek architecture, of proportion is broadly treated by Professor MARQUAND, who in default of the writings of architects and architectural critics of the Hellenistic period seems to us to attach rather too much importance to the works of VITRUVIUS, and too little to the investigations of PENROSE, COCKERELL and PENNETHORNE. Granting that the principles and theories laid down by VITRUVIUS are in the main founded on the buildings, the writings and the traditions of Greek architects, those on whom he relied belonged rather to the Hellenistic period than to the best epoch of Greek architecture. Professor MARQUAND rightly points out that what he terms major ratios and minor ratios were employed, that is, that ratios of proportion were observed between major dimensions or parts of buildings as well as between minor elements, but he

* *Greek Architecture.* By Allan Marquand, Ph.D., L.H.D., Professor of Art and Archæology in Princeton University. (New York: The MacMillan Company. 10*s.* net.)

Digitized by Google

scarcely sufficiently emphasises what seems to us a most important doctrine, which we think PENROSE has clearly established, that in any particular building, at least of the best period, harmony of proportion and hence of æsthetic effect is maintained by the use of a definite system of ratios throughout.

After proportion Professor MARQUAND takes up the subject of decoration, with which he deals in the same thorough fashion as the other divisions of his theme. He rightly attaches importance to the polychromatic treatment of decoration by Greek artists and fully explains the various types of Greek ornament, selecting his examples from all periods from the prehistoric work of Knossos, Tryns and Mycenæ, to the latest phase of Greek influence in the buildings of Pompeii.

Having thus considered the various architectural elements of Greek architecture in respect to their technique, forms, proportions and decorations, our author then turns his attention to the combination of these elements and treats of composition and style. In dealing with style, however, he omits, as many do, to point out that it affects plan as well as elevation and section, that the primal plans of Doric temples are distinct from those of the Ionic style, and are as much a mark of differentiation as the respective orders. He however makes the interesting point that the mingling of the styles of Greek architecture was from the evidence of vase paintings probably more frequent than is ordinarily supposed.

Following and completing the discussion of the means and methods of Greek architecture, Professor MARQUAND describes in a systematic manner a great number of the monuments of that activity, under the various headings of towns and their defences, water supply, religious monuments, governmental buildings, commercial buildings, buildings for physical culture, buildings for intellectual and social purposes, buildings for domestic use, and even includes the Greek methods in naval architecture and sepulchral architecture. The Professor thus disposes of the very general fallacy that Greek architectural monuments are confined to temples and theatres. He is able to do this by the completeness of the purview that he takes of Greek architecture as a whole and by full utilisation of all that has been discovered since the days of STUART and REVETT. In fine we have in this book, for the English speaking, serious architectural student, an account of Greek architecture complete and logical, comprehensive of all that has been discovered up to date of Greek work from the earliest prehistoric times to the destruction of Pompeii.

COMPETITION FOR MIDDLESBROUGH PUBLIC LIBRARY.

UNSUCCESSFUL competitors are, of course, naturally dissatisfied with the award in most, if not in all, cases, and in the case of this competition the dissatisfaction has been so general that, in addition to many letters from individual competitors, a memorial signed by 108 of the competing architects has been sent to the promoters protesting against the award on the ground that both the first and second premiated designs violated the conditions.

This memorial has been considered by the Middlesbrough Free Library Committee with considerable care and with emphatic expressions of opinion on the part of several of the members that the complaint of the memorialists was well founded.

It was brought out at the committee that the assessor, Mr. GIBSON, had been supplied with the conditions of the competition and with a copy of the replies to questions by competitors, so that he was aware of the conditions and stipulations to which competitors were supposed to work. Mr. GIBSON, knowing the conditions, made his award, which the library committee and the Town Council loyally accepted. The complaints of the protesting architects were submitted to Mr. GIBSON, and he replied by letter that he saw nothing in the conditions which would have prevented any of the competitors sending in plans on the lines of the first and second premiated designs, that the plans were in accordance with the general conditions, and that he held that the authors of the successful plans had complied with the spirit as well as with the letter of the conditions. Mr. GIBSON also sent a telegram, which we will not reproduce, as it was no doubt hastily written. It is only fair to Messrs. RUSSELL & COOPER to mention that they, in a letter read before the library committee, repudiated the statement that they had violated the conditions.

When both the assessor, Mr. GIBSON, and the winners deny that the conditions were violated, it is obvious that the library committee have done only what is right in maintaining the assessor's award.

But this does not mean that Mr. GIBSON has dealt more leniently with the infraction of the letter of the conditions than most of the competitors consider justifiable.

The source of the whole trouble is that the conditions were prepared by a committee not composed of competition experts before an assessor was appointed. Mr. GIBSON and Messrs. RUSSELL & COOPER are old hands and phenomenally successful ones at the competition game, and know perfectly well that the best design for any particular building is very often only to be produced by a wise disregard of the letter of the conditions. They, in fact, regard it as a point of the game that when the conditions are stupid they are to be evaded, of course, with as little flagrancy as possible.

The memorialists, therefore, cannot hope for any redress of their grievance from the Middlesbrough people. The only thing they can do is to bring the matter before the Royal Institute and its President, and formulate their complaint against the assessor appointed by the recognised head of the profession.

ARCHITECTURE: ITS TRUE PRINCIPLES.—XII.

By R. OWEN ALLSOP.

ARCHITECTURAL CHIAROSCURO.

THE greater part of RUSKIN's writings on architectural design seem to indicate an intense appreciation of light and shade, its disposition over buildings by reason of their masses and by solid and voids. Unfortunately for architecture in this country the effects of light and shade are not often comparable to those countries where light and shade are more highly contrasted—that is, where the sunlight is intense and shadow correspondingly impressive. Neither are atmospheric conditions so congenial. Some few days in the year we may notice those clear limpid shadows which, while dark compared to the lighted surfaces, yet are full of detail. As a general rule, the dark recesses of English architecture are covered with a blue-grey veil that hides the details beyond.

The effects of architectural chiaroscuro are referable in their root cause to the principles of contrast and gradation. The gradation on a round pillar, the flat shading of a square abacus, the blackness under a portico, the brilliancy of the most lightened parts of the column, the broad illumination of the architrave and the shade under and shadow below that, are all results of contrast and gradation.

If we regard the purest form of architecture as that which, being executed in stone or marble, is unadorned with colour, evidently the whole composition rests on the arrangement of light and shade. The work then may be more truly compared to that of the sculptor, where alone light and shade are the causes of the most beautiful effects that his chisel brings into being.

Taking this view, the building must be considered much with the eyes of an engraver or black-and-white artist. Such will endeavour to arrange an harmonious balance of light and shade, and the licence of the artist will enable him to do much to render attractive a work of architecture not, strictly speaking, well arranged in this particular.

The engraver recognises three "colours"—"black," "white," and "grey." The exact fault of a bad monochromatic drawing (after actual bad draughtsmanship) is to be "all over alike"—one tame, insipid grey tone in which—if black and white exist—they are not given their

Digitized by Google

full value. This insipid greyness we were all familiar with in the early efforts of photography.

In like manner a building may, in its light and shade, have the defect of insipidity—that is, a monotonous greyness. Now, black enhances white, and grey harmonises both, the one to the other and to itself. The opposite extreme to insipid greyness is what is called in photography a "chalky" print—hard lights and shades, ill-managed grey tones. In architecture this latter is the most common defect in its chiaroscuro, the ugly black patches and the glaring lights. Such cannot be called bold contrasts, being merely offensive, whereas the bold contrast is always pleasing. Hence we must infer that the harmonious disposition of light and shade about the building will depend upon the arrangement of the half tones. The introduction of a little grey into the chalky picture softens down the effects, and without in any way destroying the contrasts. To remedy too prevalent greyness there must be introduced shading and brilliant light—using the term to signify, the one recesses, that cause blackness, and the other projections or flat surfaces, that catch the light.

The architectural photograph may be considered as an arrangement of various patches of light and shade. Mere lines may be neglected and narrow shadows take their place. The picture formed consists, then, of masses of positive dark and positive light, with spreads of neutral

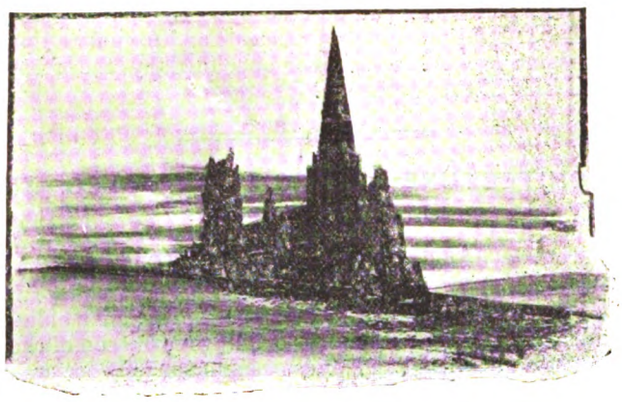

FIG. 29.

hues called grey, which may graduate from the darkest black to the lightest white.

We must for the moment neglect "proportion," because we wish to confine ourselves to the examination of the lights. If we take a genuinely ugly building—one markedly offensive to the eye—and discount the effects of ill-judged proportions (in heights and widths), we see that we have presented to us a conglomeration of ill-formed, ungraceful, harsh, on the one hand, or ill-defined, timid, half-hearted shading which, if in itself offensive to the eye, it almost necessarily follows produces light parts that must be equally offensive. What is itself beautiful cannot make its surroundings ugly. If in this manner we exhaustively study the photographs of many buildings we shall arrive at the conclusion—and this seems to be what RUSKIN intends to convey—that its beauty or ugliness reside in the shape and relative quantities of its main lighted parts and shaded parts, together with the effect of such cast shadows as are included in the picture formed. As a rule such buildings as we adjudge deficient in beauty of light and shade will be found also wholly wanting in well-considered half-tones. Fortunately for the truly sensitive eye, the passing and changing effects of light and shade and the gradation that naturally comes over a plane surface, softens down much that would be unbearably harsh. Much of the harshness of modern architecture arises from the general absence of curved surfaces with their beautiful varied grey effects.

The broad effects of light and shade that the sensitive eye appreciates at once in all old Classical architecture is killed in modern design by overloading the subject with a multiplicity of subordinate parts and details. It were as though the architect having received a commission for a considerable building, seemed afraid that if he did not do enough he would be considered lacking in ideas. Certainly a more deplorable idea never seized on any art. No noble chiaroscuro can result from the piling up of various forms and details. The more that is added the more hopelessly offensive the effect. The amount of architectural work in the Belgian Palais de Justice might be cut down to one-fourth and the building become four times as imposing in effect. To put things mathematically, one might be tempted to say that the effect of a building is inversely as the square of its elaboration. This is in a measure true—within certain limits—although in a sense it is further true that no added ornament could increase the majestic effect of a Stonehenge or of the Great Pyramid.

The reason is that we lose the broad effect of sunshine on plain orifices and shadow in plain openings. Also that every line and form added to a composition in some way (unless by design or principle necessary) decreases and detracts from the effect of those previously

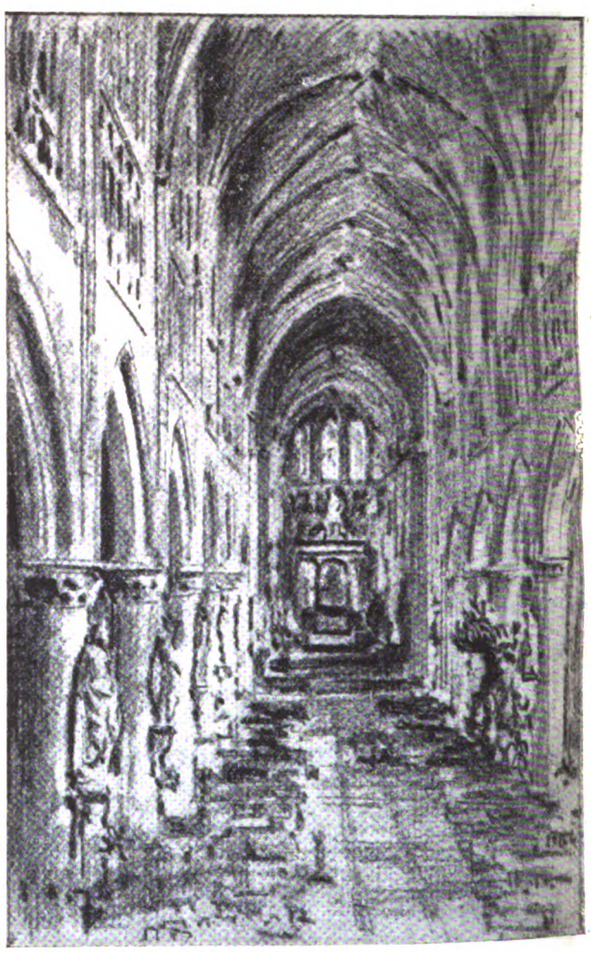

FIG. 30.—MALINES.

given. How is it then that the plain warehouse is not a fine work of architecture? The answer to this apparent paradox is doubtless that the true work of architecture "proposes an effect on the human mind, not merely a service to the human frame."

Ornament and enrichment may be disposed to give grey effects in monochromatic presentations of buildings. Thus a diapered spandrel gives a grey tone to the spandrel walls and softens the contrast between dark triforium and brilliant clerestory. A general rule might be stated that if the lights be taken care of the shadows will take care of themselves. We know this to be a good guide in monochromatic draughtsmanship. Moreover, much variety of half-tone comes naturally where there is a sufficiency of plain wall-surface. That which is a uniform tint considered as a plain superficies on elevation is not so in natural, perspective effect. Nature

Digitized by Google

always harmonises by half-tones, so that the main thing is the light. Shadow like trouble must come so that the thing is to make the most of the happy moments. Moreover, it is a fact that (all things being appreciable mainly by contrasts, as heat to cold, round to square) to obtain brilliant lights, shadows must be introduced. Without such there can be no sunshine effects, and hence we may consider that to take care of the lights means in reality *the careful introduction of dark parts*. In an ugly building such will be great square black patches repeated *ad nauseam* as in a "sky-scraper."

It may be possible to suggest some slight illustration of the above remarks. Fig. 29 has the three primary engraver's colours plainly marked. Fig. 30—no doubt principally owing to bad drawing, if in part also to the presence of sculpture on the pillar shafts—is essentially "all-over-alike"—spotty; whereas in fig. 31 the light and shade masses, at any rate more effectively than in the other drawing. Fig. 32 is in three colours, more exactly so than in the case of the other illustration given, where there is

FIG. 31.—GREAT YARMOUTH.

some little variety of grey. The examples primarily concern drawing, it may be urged. To appreciate their bearing on actual design needs deductive, analogous reasoning. The general indication is that what is required is focus, concentration, and condensation, as distinct from "work" of equal, monotonous value in all parts.

Monotony, with hard outline, seems the most objectionable attribute of a building. It is common in questions of design to refer to lines of light and breadths of light, but not sufficient attention seems to have been given to

FIG. 32.—PETERBOROUGH.

what may be termed "broken" light, best seen, perhaps, in a summer sky with fleecy clouds, and most beautiful when graduating from great masses into cloud dust, as it may be termed. This is a direct and pure contrast to the broad stretch of light or shade. We are conscious of this broken-light effect when before an elaborate building, such as a rich Flamboyant cathedral front, or we need go no farther than our London Eleanor Cross. In such work the fullest value seems given to the contrast of richness of detail with simplicity of mass. Again, geometrical regularity of dark and light—as in window tracery—contrasts with irregular, broken light and shade, and the enhancement is mutual. Most principles of design bear upon, as foundation, what may be called contrast, relief or comparison. The physiological basis seems to be that, if we continue to look at what is round, we gradually lose the appreciation of roundness and must restore the balance by beholding squareness. For a similar reason, doubtless, if we gaze long at a word, we may note that it gradually tends to become an uncouth, meaningless sign.

The relative shapelessness of a shadow enhances the geometrical regularity of the object itself. It would seem that whereas, as children, we learn to draw and shade cubes, prisms, spheres and cylinders, we do not thoroughly investigate the nature of the lights and shades about such objects; so that their æsthetic value is not, in later life, understood. Yet if we decompose, as it were, architecture it is found to be built up of combinations of these elementary forms, and such may perhaps be assumed to be its true atoms. A brick or a stone block has its practical value in building. Its form and light and shade effects constitute its architectural value.

(*To be continued.*)

THE HAMPSTEAD GARDEN SUBURB.

FOR some three or four hundred years Hampstead has been known to Londoners as a place of refuge. Indeed it is not improbable that before even the days of the Norman invasion it had come to be regarded as a haven of rest from the toil of city life. Edward the Confessor is believed to have gifted it to the monks of his Abbey of Westminster, and their rights were respected by the Conqueror. The royal munificence was repeated some centuries later when Henry VIII. assigned the manor for his new bishopric of Westminster. It was during his reign that, in consequence of a prophesied inundation, large crowds fled from the city and encamped on the heights of Hampstead. Similar scenes were witnessed at the time of the Great Plague and the Great Fire.

Both Henry VIII. and James I. were attracted to the district for the sport it offered. It appears to have been in the time of the latter monarch that Hampstead suggested itself as offering delectable sites for country villas. At the end of the seventeenth century some 260 houses were erected there and from thenceforth it became more and more fashionable. The world of art set the seal of its approval on it. George Romney erected a house from his own designs and under his personal supervision at a cost of 2,733*l.* on Holly Bush Hill. In the plan everything was made subservient to the studio and gallery; in consequence, on the death of this fashionable portrait-painter, shortly after its completion, the house could find no purchaser, and was replaced by an assembly room. A still greater enthusiast was John Constable, who had a house in Well Walk, the little drawing-room of which commanded "a view unsurpassed in Europe—from Westminster Abbey to Gravesend. The dome of St. Paul's in the air seems to realise Michel Angelo's words on seeing the Parthenon, 'I will build such a thing in the sky.'" Sir Gilbert Scott and his son George Gilbert Scott resided there many years later. Writers as well as artists were attracted to the place. It is however as a resort for the many rather than for the select few that we now wish to consider Hampstead.

The Heath is generally regarded as the loveliest of London's open spaces. In 1905 the Hampstead Garden Suburb Trust proclaimed its policy as to dealing with the land that lay to the westward of the Heath. In the course of their letter they said:—

"Our aim is that the new suburb may be laid out as a whole on an orderly plan. When different plots are disposed of to different builders, and each builder considers his own interest, the result is what may be seen in the unsightly modern streets. Our hope is that every road may have its own characteristic, that small open spaces may be within reach of every child and old person, that no house may darken or offend a neighbour's house, that the whole may be so grouped round central features and central buildings,

Digitized by Google

and that from every part there shall be good views or glimpses of distant country. We believe that the successful example of such a plan of town development might take away some of the anxiety now caused by town extension. We aim at preserving natural beauty. Hampstead Heath, by reason of the spacious views it offers, is a resort for Londoners which is yearly more appreciated. If the Eton College Estate, occupying as it does the foreground of the wide western view, is covered with the usual long, narrow

THE HAMPSTEAD TENANTS, LTD.—COTTAGES IN HAMPSTEAD WAY—RENTS FROM 6*s.* 6*d.* TO 8*s.* 6*d.* PER WEEK.

streets, or built over by block dwellings, much of this attraction will be lost. Our object is so to lay out the ground that every tree may be kept, hedgerows duly considered, and the foreground of the distant view be preserved, if not as open fields yet as a gardened district, and the buildings kept in harmony with the surroundings."

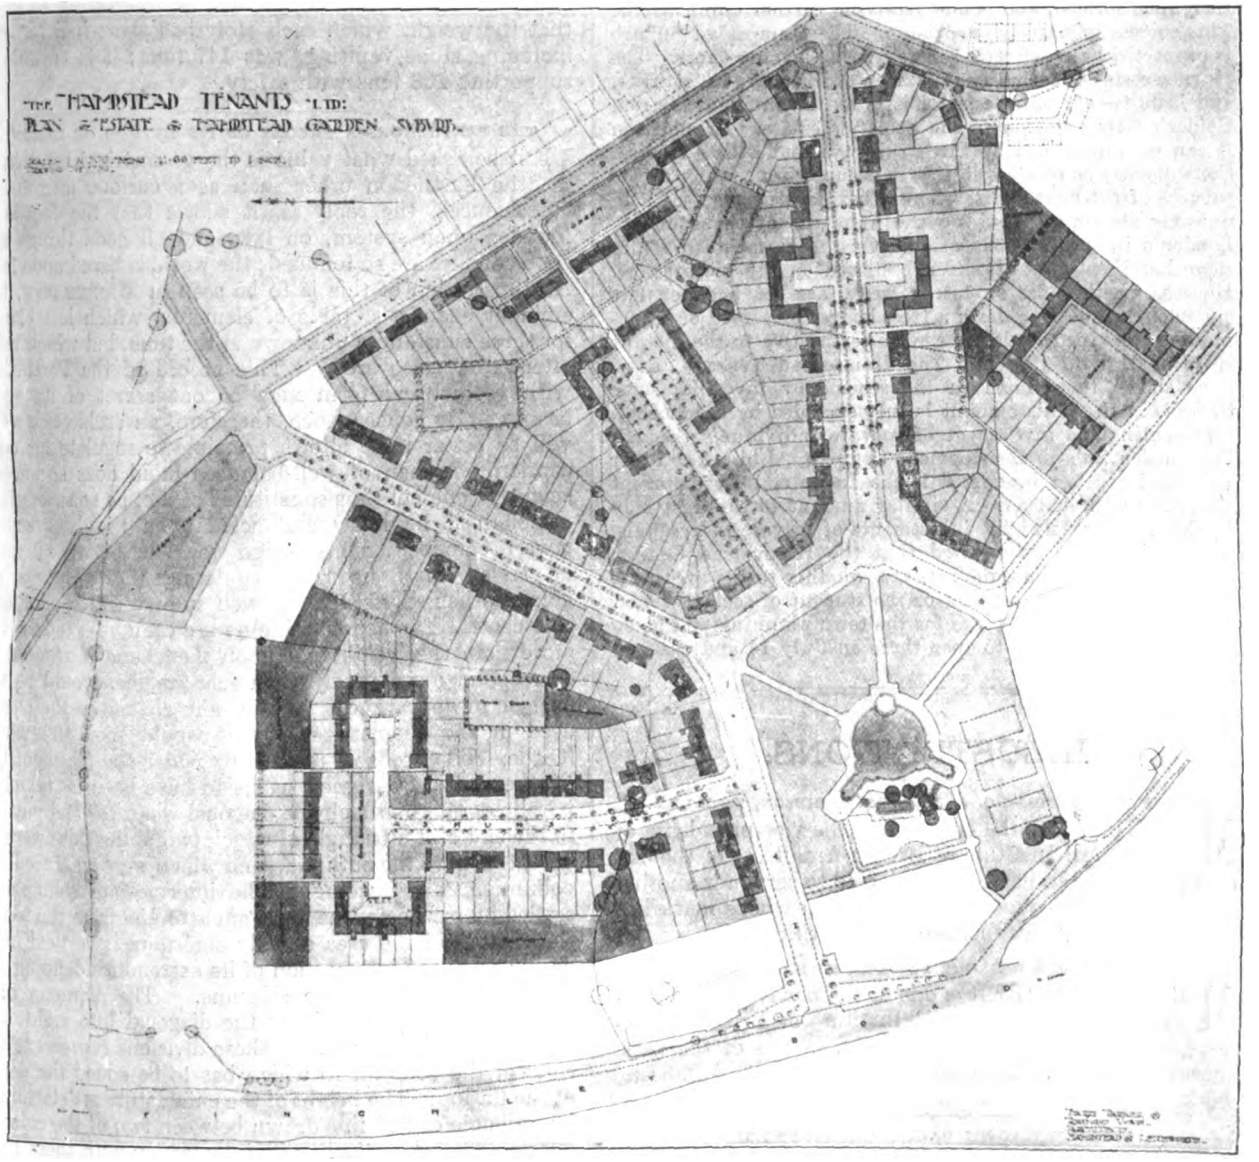
This ideal was rendered substantially nearer of attainment when in May 1906 the Hampstead Garden Suburb Trust, Ltd., was formed, under the presidency of the Right Hon. Alfred Lyttelton, K.C., M.P., and when, shortly after, the 240 acres were purchased for 112,000*l.* from the Trustees. Of this area eighty were added to the Heath. In May of the following year the Hampstead Tenants, Ltd., began operations, and in March 1908 it was followed by the Garden Suburb Development Company. The general scheme for both was prepared by Messrs. Barry Parker & Raymond Unwin, in consultation with Mr. E. L. Lutyens. It was, of course, considerably controlled by the Hampstead Garden Suburb Act of 1906. Of the Hampstead Tenants, Ltd., we shall speak later.

(1) THE GARDEN SUBURB DEVELOPMENT CO. (HAMPSTEAD), LTD.

The Development Company have since obtained the co-operation of a large number of other architects in the preparation of designs for houses. They include Mr. Michael Bunney, Mr. Courtenay Crickmer, Mr. E. Guy Dawber, Messrs. Horace Field & Simmons, Mr. W. Curtis Green, Mr. P. Morley Horder, Messrs. Joseph & Smithem, Messrs. Langley & Baines, Mr. Geoffry Lucas, Mr. Arnold Mitchell, Mr. M. H. Baillie Scott, Mr. C. Harrison Townsend, Mr. W. H. Ward, M.A., Mr. Edgar Wood. Building work was begun in March 1908, and already over sixty houses are in occupation and nearly the same number in course of erection. Their values vary from 350*l.* to ten times that amount. All the houses have been erected by the same contractor—W. Moss & Sons, Ltd.—whose tender was the lowest in the first instance, and from which a schedule of prices has been drawn up as a basis for future work. The illustrations distributed throughout our pages show a few of their houses. The site conditions are of the happiest.

COTTAGES IN ASMUN'S PLACE.

Digitized by Google



The names of the architects are a guarantee that nothing would be done to create a discord with the beautiful surroundings. The Development Company, it should be here explained, control an option not over the entire estate, but only over a portion of it. Intending owners may inspect the plans already in the possession of the company, or they may put forward plans by their own architect, which (after they have obtained the approval of the ground landlords, the original Trust) are then carried out by the company's builders. The company is not a philanthropic one, but a commercial concern, which realises that the beautiful may be exploited in estate development.

(2) THE HAMPSTEAD TENANTS, LTD.

When the Trust acquired some 240 acres from the Eton College authorities they stated:—"We desire to do something to meet the housing problem by putting within the reach of working people the opportunity of taking a cottage with a garden within a twopenny fare of central London and at a moderate rent. . . . We desire to promote a better understanding between the members of the classes who form our nation. Our object, therefore, is not merely to provide houses for the industrial classes. We propose that some of the beautiful sites round the Heath should be let to wealthy persons who can afford to pay a large sum for their land, and to have extensive gardens." The first portion of this article has dealt with a company concerned with the erection of houses of the more expensive class. But the idea of the promoters when they acquired the 240 acres was to do something besides that, for the provision of houses costing 350*l.* or 3,500*l.* offers not the slightest help towards a solution of the housing problem. That side of the scheme comes within the range of the Hampstead Tenants, Ltd.—a branch of the Co-Partnership Tenants, Ltd., a society which very successfully endeavours to solve the housing problem on commercial principles. The Hampstead Tenants, Ltd., has been organised to return a profit to those who invest their money in it. But that profit is limited to 5 per cent., while any surplus profits are added to the shares of the tenant members as a dividend on rent. Their scheme is an interesting one, and may here be accorded a little of the attention and examination that its organisers invite. The share capital is in shares of 10*l.* each, payable in full, or 5*l.* on allotment and the rest by instalment. The maximum dividend is, as already stated, 5 per cent., and past experience has clearly shown that this will be well within the profits. The Society has power to raise loan stock, on which 4 per cent. is paid; this interest is met before any dividend is declared on the shares.

Every prospective tenant must become a member of the Society by the investment of 5*l.* in the shares before he can take one of their "substantially built houses, provided with good sanitary and other arrangements." He then pays a fair market rental (which, in comparison with the rents of the ordinary suburb, must seem a low one), plus a regular sum for rates and taxes. The surplus after the charges have been met is credited to him in proportion to his rent. These profits, however, are not paid out in cash, but are credited to him as share capital, so that the tenant can never become the owner of his house, but he does become, in course of time, the owner of the value of the house, this being represented by shares, which will find ready purchasers inside or outside the Society. If they are retained, the 5 per cent. interest paid on them can be set against the weekly rent. This accumulating share capital also acts as a reserve which may be drawn upon for the payment of arrears of rent.

All external repairs are carried out by the Society; the internal repairs are done by the tenant, or, if necessary, by the company, who deduct the cost from the tenant's rent bonus. The social life that is aimed at is that of a large

Digitized by Google

happy family enjoying in common means of indoor and outdoor recreation. The end of one vista is closed in by a range of houses under one continuous roof and with slightly projecting wings, while in front is a bowling green. In another case the houses are laid out round three sides of a triangle, with gardens converging into a tennis court. It is noteworthy that the backs of these houses are no less picturesque than the fronts, and are entirely free from the customary hideous outbuildings. The first part of a social institute has already been completed, and a club is now in course of erection.

In May 1907 Mrs. H. A. Barnett, a lady who figured very largely in the inception of the entire Garden Suburb scheme, cut the first sod, at the invitation of the Hampstead Tenants, Ltd. Since then the houses have been erected with all possible speed, though not fast enough to cope with the demand. When the number of applicants exceeded the supply of dwellings by a hundred it was announced by the Society that they would receive no further names. A second Society, called the Second Hampstead Tenants, Ltd., was thereupon formed, and is now receiving further applications. This success is scarcely surprising. The Hampstead Suburb is connected by an electric railway with Charing Cross. The journey costs 3*d*. each way (workmen's tickets are 2*d*. return), and lasts twenty minutes, and it is ten minutes' walk from Golder's Green station to the Society's estate. In addition it can be approached by three railways and a 'bus service. Consequently as to accessibility it is superior to many of the suburbs of the metropolis, where a bewildering maze of long unlovely streets swallows up the hundreds of thousands of London's industrial population. On the Hampstead estate there has been close attention bestowed on the picturesque. Houses, whether 6*s*. or 15*s*. a week, are set back or left out to obviate cutting down a tree, hedges preserved or transplanted; one road leads the eye in perspective to the distant spire of Harrow Church. The Hampstead Tenants, Ltd., have shown their faith in the scheme by investing some 80,000*l*. in it. This amount is only exceeded by the 85,000*l*. representing the investment of private individuals through the Garden Suburb Development Company, Ltd. The other principal concern interested is the Industrial Development Company with 40,000*l*. A similar amount to this last may be taken to represent the investments of private individuals. It may be confidently stated that the Hampstead Garden Suburb possesses a unique interest, whether to the architect, the houseowner, the artisan, or the student of social science, and is a most suitable place for the town-planning and housing exhibition that is to open there on July 14 and close on August 7.

ILLUSTRATIONS.

LIVING ARCHITECTS.—NO. 8, MR. J. G. S. GIBSON, V.P.R.I.B.A.

MR. GIBSON is the only one of the vice-presidents of the Royal Institute of British Architects of the expiring session who has been re-elected to serve for another year. He is, of course, one of the men whose mark has been made chiefly by success in competitions.

NO. 9, MR. E. GUY DAWBER, V.P.R.I.B.A.

MR. GUY DAWBER is one of the newly-elected vice-presidents of the Royal Institute of British Architects, and, as all our readers know, is one of the most successful of our modern architects in the field of domestic work.

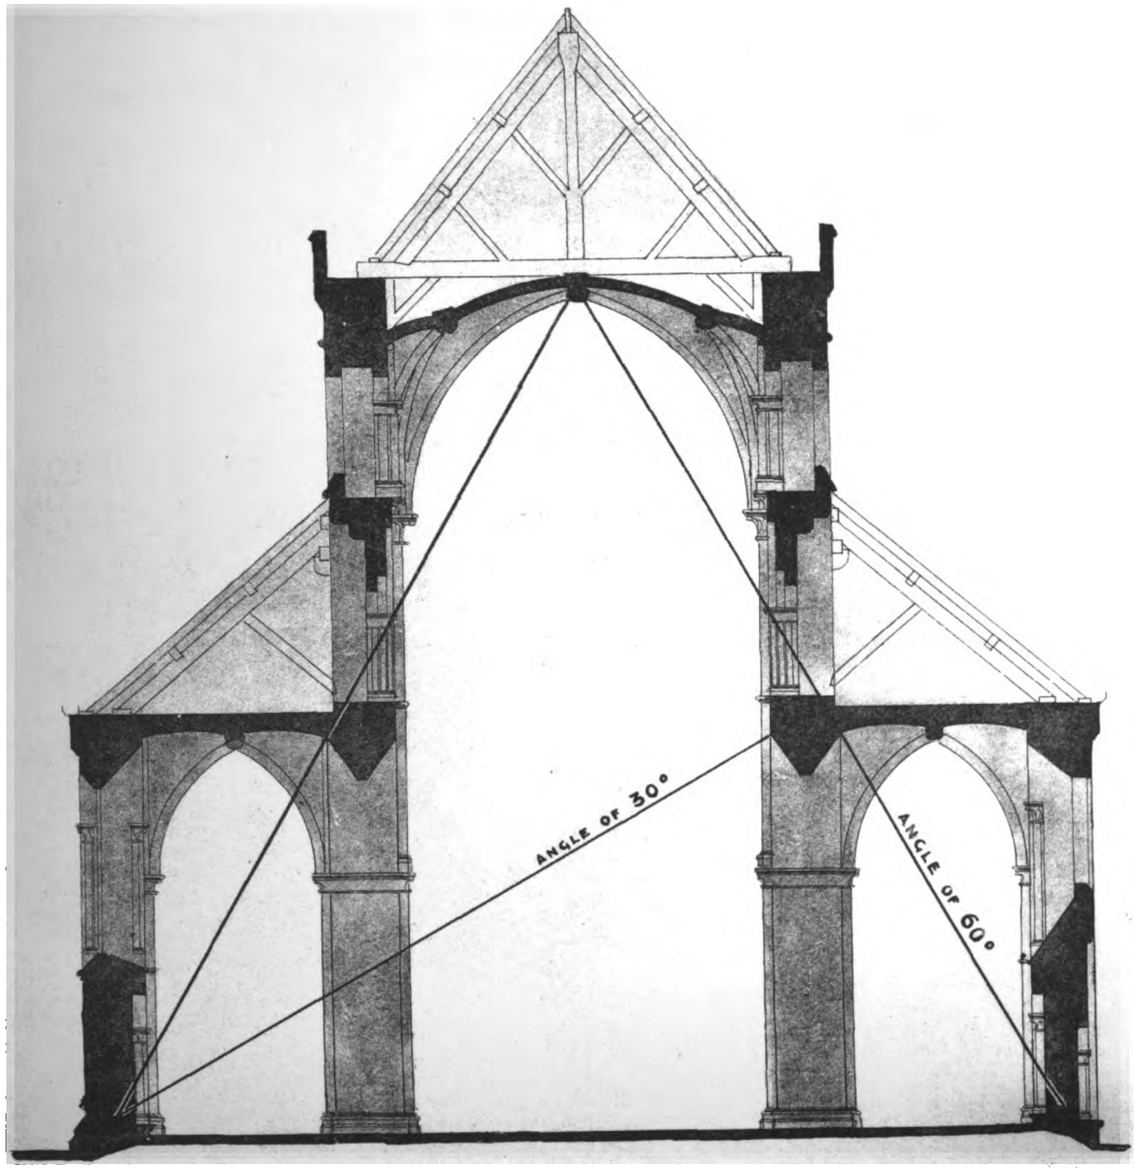
STOCKPORT TOWN HALL.—THE GREAT HALL.

IN previous issues photographs have appeared of the main front and the council chamber of the Town Hall at Stockport. The great hall here illustrated is 114 feet long by 62 feet wide and 41 feet high, with a seating capacity of 1,250 on the floor level. There is a large stage at one end and a gallery seating 147 at the other. Behind the stage is placed the stage ante-room and dressing-rooms, the former 38 feet by 25 feet. The hall is divided into seven bays; both the entablature and curved ceiling, which is supported on large piers, are executed in richly modelled cast fibrous plaster work, special attention being given to the elaboration of the ventilating openings in the ceiling. Particular attention has been paid to the provision of sufficient fire appliances. The contractor was Mr. JOSIAH BRIGGS, of Stockport. The architect is Sir A. BRUMWELL THOMAS.

INTERIOR OF HOLYROOD ABBEY CHAPEL.

HOLYROOD ABBEY.—A THEORY OF ITS METHOD OF DESIGN.

THE diameters of the solid of the Holyrood Chapel columns are found by the same method which determines those of the Parthenon, viz. by passing a line at an angle of 60° across one of the bays and dividing it into seven, the number of columns in the nave; the result is the solid of the column. The same principle applies to Westminster Abbey, taking ten as the number of divisions, to Lincoln nine and to Southwell six divisions. The divisions in the three latter cases were made from small scale drawings, and it would be desirable to test the theory by means of large scale diagrams by anyone who has the material for their preparation. The transverse section of Holyrood Chapel is founded upon an equilateral triangle, and, as is well known, this form of triangle is applicable to much of the mediæval work, such as Westminster Abbey, Southwark Cathedral, Milan, and the Byzantine church of Santa Sophia. It will be interesting to know that the weight which each Holyrood shaft had to bear, including stone vaulting, was 147 tons; it is capable of supporting 208 tons with safety.



THE PARTHENON.—A THEORY OF ITS METHOD OF DESIGN.

IF it be asked what value is the geometrical solution of the Parthenon other than as a curious diagram of coincidences, the reply is, it shows that the façade is founded upon system, on law, and all good things and good conduct are so founded; the world is based upon law. An illustration of this is to be seen in MENDELIEFF, the eminent chemist's, table of elements, which left blanks for three substances unknown at the time, but which were afterwards discovered. This accord of the Parthenon with geometrical form may be one secret of its great beauty. By consequence, therefore, an architect's work will be better if he allows principle to regulate his conception. A man of well-balanced mind does so unconsciously; one not thus constituted cannot be so successful, although if he knew and acted upon the laws which govern composition his design would be better. It may be added that the rule regulating the diameters of columns has an æsthetic as well as practical application. The central Parthenon columns are each able to bear far more than the weight put upon them, and if reduced to correspond more nearly with that weight, would be too slender in appearance. Again, any change in the angles used in the geometrical figures would spoil the whole façade. The probable method by which the façade of the Parthenon was designed seems to have been by taking a parallelogram of which the diagonal was 22½° and putting to the end of it a triangle of which two of the sides were of 45°; this gave the outline within which were embraced the columns. The spacing of the intermediate columns is settled by passing a line at an angle of 45° from the top to the bottom of the area already determined, vertical lines drawn from the intersection of its extremities defining the space occupied by three columns. The diameter of a column is fixed by dividing the diagonal into eight, the number of columns; one of these divisions represents the solid of the column, to which has to be added the depth of the fluting. The height of the entablature is determined by an angle of 60° line drawn between two of the column lines continued vertically; its intersection with these lines fixes the height. The underside of stylobate is found by forming a square having for its three sides the top of the cornice and the lines bounding one-half the front. The top of the pediment is determined by taking one-half the frontage at the level of the top of the columns, and on this erecting the other two sides of a triangle at an angle of 45°, or alternatively by placing a triangle having the same base with its other two sides at an angle of 30° on the top of the cornice. The above suggested geometrical theory relating to the Parthenon was arrived at after finding that Mr. D. R. HAYS's system of angles did not work out with accuracy; and was reached in the course of preparing a lecture on "How to Know Good Architecture," which was delivered to the Scottish Industrial Art Association by Mr. G. S. AITKEN, and which we give elsewhere in this week's issue.

CARPENTERS' HALL, LONDON WALL.

CARPENTERS' HALL AND DRAPERS' HALL.*

Carpenters' Hall.

THIS building is quite modern, dating from 1876, when the old hall and building founded and commenced in 1428 were demolished. The latter are stated to have been a medley of style and perhaps of construction, and while perhaps the requirements of the company had out-grown them one cannot but regret their disappearance. There have, however, been preserved three most interesting frescoes, which formerly adorned the wall of the Livery Hall and represent:—(1) The repair of the Temple by King Josiah, who is shown giving directions to carpenters, wherein it is stated that no bargain was made, because they dealt justly; (2) Christ in the carpenter's shop at Nazareth; and (3) Christ in the synagogue when the cry was raised, "Is not this the carpenter's son?" A fourth fresco was originally there representing Noah constructing the Ark, but that fell to pieces, and we can only see a copy. The remainder, however, are in good preservation. They are painted on plaster laid on a sub-stratum of loam and straw held up by wattles.

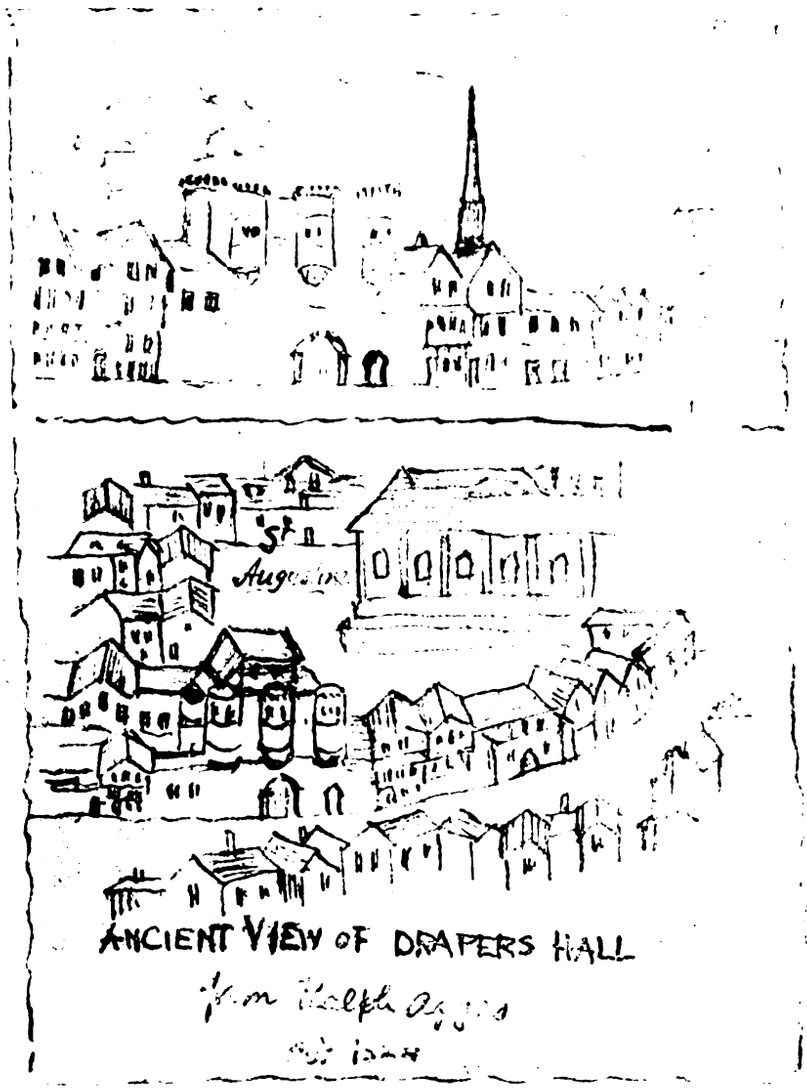
How this composition was successfully removed and framed entire is a marvel and a tribute to the skill of Mr. Pocock, the architect, and all engaged upon the work.

These frescoes date approximately from early sixteenth century and were doubtless canvassed over and covered at the Reformation period, subsequently forgotten and not rediscovered until 1845.

There are some wardens' caps or crowns dating from 1561 and still in excellent order. The master's silver drinking cup is dated 1611, and those of the wardens 1611, 1612 and 1628 respectively. Formerly the junior warden was expected to make on election some gift of plate, and these took the form of silver apostle spoons. Several mentions occur in the books as to these. There is also a very good octagonal Jacobean table dated 1606, also the master's State chair, with back of richly carved mahogany, but its date is doubtful. The company's charters also are preserved. The Carpenters had a large garden which abutted on that of the Drapers' Company, and which is mentioned from time to time in the company's books. It was used for the pleasure and enjoyment chiefly of the master and wardens, who at one time had the privilege of using it as a drying ground. Although the great fire of 1666 very nearly approached the old buildings, they happily escaped only to be demolished two centuries later to make room for the present buildings.

Drapers' Hall.

Like that of the Carpenters', this hall is of modern construction, having been almost wholly rebuilt in the early seventies. Portions, however, of an older construction remain, which date from 1774. These are the walls of the court dining-room, and those of the court room, abutting upon Throgmorton Avenue, and in the latter room are to be seen the original plaster frieze and cornice, as well as



* Part of a paper read at a meeting of the Upper Norwood Athenæum by Mr. Frederick Higgs.

Digitized by Google

the beautiful oak doors, architraves and linings, and also the window linings of the earlier buildings referred to.

The new buildings of 1872 are of an excellent character, and there is some beautiful work in them. They follow mainly the old lines which were laid down when the original building on this site (formerly the mansion of Cromwell, Earl of Essex) was destroyed by fire in 1666. The designer of the buildings then erected was Jerman, architect to the Fishmongers' Hall. They have been described as forming a lordly palace with quadrangle and piazza brick faced internally, and containing all the usual rooms and appurtenances proper to a company's hall.

There are to be seen in the Drapers' buildings a large number of valuable works of art, notably four tapestries covering portions of the walls of the court room and the drawing room, representing scenes in the story of Jason and Medea. These tapestries, originally made at the famous Gobelins factory during the later years of Louis XV., were given by his son Louis XVI. to the then Spanish Ambassador to France, passing from him to the Marquis of Salamanca, who sold them to Mr. Colman, of Stoke, near Slough, who, in turn, disposed of them to the company in 1881. They are very beautiful specimens of the art.

On the ceiling of the Livery Hall are three exceedingly good modern paintings by H. J. Draper; they are painted upon canvas secured to the ceiling, and represent scenes from Shakespeare's "Tempest" and "Midsummer Night's Dream." They also may be taken to represent in a minor form, "Morning," "Noon," and "Night." They are very beautiful productions, and it is a pleasure to reflect that they are the work of a British born artist.

In the other rooms are various oil paintings of royalties and notable members of the Drapers' Company by well-known artists. Over the door in the court dining-room is a picture representing the Holy Family, in beautiful colouring, by an artist of the school of Giovanni Bellini.

There are also sundry pieces of statuary and busts of a very high order of sculpture, and also the celebrated statue of Hypatia by Richard Belt, which was the subject of a celebrated law suit.

The original hall, destroyed in the Great Fire, was a very extensive place, and is shown on the sketch map of London by Ralph Aggas, published in the sixteenth century.

There was a three-storey castellated and turreted building in the front, under which the gateway passed leading to a courtyard, across which the visitor passed to the Great Hall building with a winding staircase up to the Banqueting Hall in the upper storey. The sides of the courtyard were probably enclosed with subsidiary buildings, thus forming a quadrangle. It will be seen, therefore, that these formed most commodious premises for the company, and were of the Baronial Hall type as befitted such a nobleman as the Earl of Essex, who built it in the first instance.

Previous to coming to the Throgmorton district, the Drapers were located (1477-1541) in St. Swithin's Lane nearer the centre of their trade, which at that time was practised in Candlewick (now Cannon) Street and Cheapside.

Attached to their hall and premises in Throgmorton Street was a large and beautiful garden which existed right up to the rebuilding in the seventies, and the present kind and genial beadle speaks with regret at its disappearance, as until the date of its being built upon he lived on the spot and enjoyed its pleasant seclusion. But City land is too valuable for horticultural purposes.

The Trade Guilds of Carpenters and Drapers.

These two organisations, like all the City guilds, were formed early on in the feudal times for the regulation of the practice of the art, mystery, or trade involved, and for the protection of the members using the craft. The Drapers must have been organised in this way very early on, because we find that Fitz-Alwyn, the first Lord Mayor of London, in 1189, was a draper, and left goods in trust with or for the benefit of his trade. The Charter of Incorporation is dated 1364. That of the Carpenters 1477.

These charters were confirmed and the rights, privileges, and duties conferred thereby enlarged or extended by other charters of later reigns. They gave powers which could be and were enforced by the civil authorities for the due, proper, and equitable practice of the trades, permitted the courts of the companies to make by-laws setting up standards of weight and measure, and enabled them to enforce these rules by fines and other forms of punishment. The charters further made it easy to provide for the continuity of the trade by the establishment of bound apprenticeship, and guarded against over-competition and maintained the closeness of their fellowship by duly limiting the number of such apprentices.

All this regulation was according to the charters permitted because "divers work or workmanship in the mystery have oftentimes heretofore been made and daily are made insufficiently which, if it should be suffered to be so done would redound not only to our prejudice, but also to the manifest deceit of our liege people."

Then it states that this proceeding is "for the praise, glory and honour of the omnipotent God and of the glorious and undefiled Virgin Mary."

Both companies' charters run on the same lines in respect to this dedication and also as to their rights and duties, and as in those days the outward profession of religion was more allied to the practice of everyday business than in these times, so we find that all the meetings of the courts and companies were preceded by a visit to church to hear Mass sung for those members passed away and for the living also, after which the business of the craft would proceed, followed by refreshment and jollification.

Drapery in these early days comprised clothmaking and tailoring, besides, as it was invented from time to time, the lighter kinds of merchandise we now know under the term, so that naturally the Drapers were one of the most important of the trade guilds. Similarly the Carpenters were very powerful as representing what we should call to-day the building trade, because houses in the eleventh to the sixteenth centuries were almost wholly of framed timber, the

Digitized by Google

panels being filled in with wattles and daubs and later of brick. As building developed their monopoly ceased, brick and stone and tile being introduced, giving rise in due course to rival guilds in the form of the Bricklayers and Tilers', Masons' and Daubers' (or Plasterers') Companies. Further division also arose in the distinction between Carpenters and Joiners, and the latter craft presently formed themselves into a guild, so that the power of the Carpenters waned considerably towards the end of the seventeenth century, and we find that in that following their powers of regulation, if not of apprenticeship, had lapsed almost entirely.

Both guilds without a doubt exercised a wise and salutary influence in their day and served a most excellent purpose, but the progress of independence in thought and action and encouragement of individual effort left them in due course high and dry, and either from selfishness on the part of the management or carelessness on the part of the craftsmen of the day, the membership of the guilds gradually broadened, so that to-day it is by no means necessary for a Draper to be a draper or a Carpenter to be a carpenter. Hence many people have averred, and not without some justification, that funds which were evidently originally left for the benefit of craftsmen of the trades practised were being used for purposes far removed from such an end. This is only partly true, however, because both the Carpenters and the Drapers do a vast amount of educational and philanthropic good with the resources at their disposal, the Drapers maintaining up and down the country as many as five free schools, eight institutions of almshouses, one hospital, three sets of lectures and two University exhibitions. The Carpenters similarly maintain almshouses at Godalming and Twickenham, maintain evening schools for the theoretical and practical teaching of youths engaged in one or other branch of the building trade, and are liberal supporters in prizes at the annual examinations at Kensington of the City and Guilds Technical Institute, which I believe it contributes largely to maintain.

The funds belonging to the Companies have grown immensely with the growth of London and the increased wealth of the country generally, having arisen from judicious investments in freehold and other properties. Properties left in trust 400 or more years since for the benefit of the craft generally have increased in value manifold. Much was left also in trust for the saying of Masses for the greater comfort of deceased members, but this was all seized by the Crown in 1554, with the option to the Companies to redeem at twenty years' purchase, and the exercise of this no doubt proved in every case a most judicious outlay. In conclusion I have to tender my sincere thanks to the courteous clerks of both Companies for the kind assistance they rendered me in the preparation of the subject, and to the genial beadle of the Drapers' Company, Mr. Chipperfield.

HOW TO KNOW GOOD ARCHITECTURE.*

By MR. G. S. AITKEN.

WHEN asked to give a lecture to your Association, I thought a few remarks on the principles of architectural design would enable you to understand architecture better and to enjoy more the good examples which will necessarily come under your notice whether you stay at home or travel.

I propose confining your attention more immediately to Edinburgh examples, and those, for a very obvious reason, not the works of living architects. Naturally these will belong to the two great styles of Classic and Gothic, and we cannot do better than begin with the National Monument on the Calton Hill, as amplified in the Royal Institution, and Holyrood Abbey Chapel.

The National Monument was intended to be a copy in size and detail of the Parthenon at Athens, an example of pure Greek art of the date 438 B.C., and the result of much that had gone before.

Beginning with the west façade and completing it by reference to the smaller work at the Mound (excepting, of course, the statue of Her late Majesty, the wings and sculptured details), we note that it consists of eight columns resting on three steps, carrying an entablature and pediment: a beautiful building in three parts. Let us try to discover the source of this beauty.

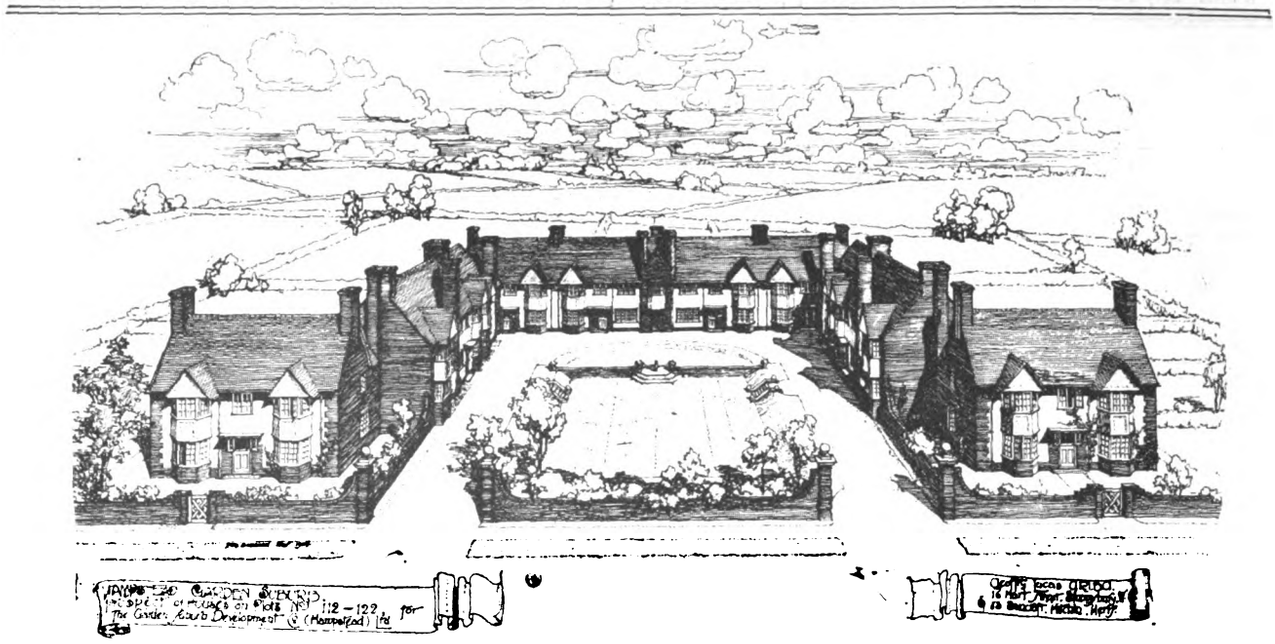
One reason is that there is a commanding feature—the column—to which the other parts are secondary, and this principle of domination is always an element in good architecture. It is absent in the graceful building of the Life Association of Scotland on the opposite side of the street, and so far the pure Classic example has the advantage. On the other hand, the law of compensation is here well illustrated in the singular beauty in each of the two upper storeys, which with the rest of the façade are founded upon the Palazzo Pesaro at Venice.

The columns of the Parthenon are tree-like in form, wider below than above; this introduces a living sentiment into them and also prevents them appearing top-heavy, which they would have done if they had the form of parallel cylinders. They differ from the tree in that they are not straight-sided, having a slight swelling or entasis tending to correct the optical illusion of hollowness which the straight line would have given. They have no base, and in that are quite singular. It is only necessary to imagine the addition of a base to show that the Greek was quite right, and if anyone, for the sake of originality, introduced one, we may be sure that his example would find no followers.

The true base of the column is the stylobate, consisting of three steps which carry the outline of the columns to the ground, having their counterpart in the tree stem with its basal curve suggestive of stability.

The column has not a plain but a fluted surface. The only plain example is to be found in the Isle of Delos, but the intention to apply flutes there is evident, as the beginnings of them occur at the top and bottom. The reason for these flutes is threefold:—(1) They give variety to a surface which without them would be uninteresting; (2) they give the appearance of added strength; and (3) are a means of contrast between the plain lines of the stylobate below and of the architrave above. The flutes have very likely been suggested by some form of vegetable growth, such as the "heraclium" or "cow-parsnip," which is ribbed with a similar section of flute. It is interesting to note the exactitude of Nature's method of construction. If you cut through a large and small section of heraclium you will find the thickness of outer skin in proportion to the hollow precisely the same in both cases—viz., one-eighth of the diameter. The plant has twenty-five, the column twenty, flutes.

The column has a capital in three parts—viz., a ring of annulets immediately above the flutes which binds the neck and serves as a base to the echinus, a moulding of refined contour passing into the square block which crowns the shaft. There is in this no redundant detail; everything has a reason for its presence, the moulding apparently bending under the entablature and yet suggesting its ability to do the work. Or we may regard the annulets as calyces out of which the fluted shaft buds, which, though restrained from development by the square abacus above it, yet gives a sense of vitality to the column, just as in Pointed architecture the clustered shafts burst forth into foliage, flower and protecting abacus out of which spring the arch moulds.



From what has been said we note how a law of three pervades the work; it is exemplified in the entablature, which is divided into architrave, frieze and cornice. The architrave, but for bronze inscriptions or other devices which have apparently been fixed to it, is plain and balances the stylobate. The triglyphs are difficult to account for; some say they represent the ends of wood beams which supported the roof of a prior wooden structure, but this is very unlikely, as they appear on the front where no beams would be, as well as on the sides where they would occur. They seem to be rather vertical lines in contrast with the horizontal lines of the entablature, and are connected with the architrave by little pyramidal drops which break the otherwise stiff line at the top of the architrave; by means of the mutules on the cornice soffit the triglyphs become with the drops a kind of bracelet uniting architrave, frieze and cornice. The interspaces or metopes are exactly square, filled in with sculpture so arranged by means of various angles as to unite the triglyphs together. The originals of this sculpture, known as the Elgin marbles, are now in the British Museum.

In the Royal Institution are wreaths instead of sculpture, which more economically fulfil the same purpose though not so effectively. The Parthenon pediment has sculpture symbolical of Greek mythology. In the Edinburgh example conventional floral forms take their place, and are sufficiently decorative without having, unfortunately, any meaning relative to the purpose to which the Institution was to be put.

The flatly inclined pediment fittingly crowns the front, harmonising with the prevailing horizontal lines. But if we ask if all this in the case of the Royal Institution be good architecture, we must give a qualified answer. The flat roof

* A lecture delivered to the Scottish Industrial Art Association.

Digitized by Google

is not good for our humid climate, as it would allow of no other waterproof covering than such as lead, copper, or asphalte; we are shut out from slate. The carving is inappropriate, as it does not indicate by any symbolism the purpose of the building, and is simply a piece of excellent drawing.

It was a happy inspiration of Playfair's to place the statue of Her late Majesty on the summit. The outline of the building from Hanover Street is singularly fine. It would have been better, however, if the statue had been at the south end facing the sun. The southern façade would in this way have been a joy for ever.

Classic architecture for any modern purpose has this defect—that its heavy entablature casts a shadow on any windows there may be below and prevents the architect securing the full advantage of the interior. Indeed its use reverses the order in which buildings ought to be designed, which should be from the interior outwards; pure Classic compels study from the outside inwards.

As in the Parthenon, so we find the law of three prevailing in mediæval ecclesiastical architecture, and in Holyrood Abbey Church, when in its complete state, in the transverse division of nave and aisles, the longitudinal of choir crossing to nave, and the vertical of nave arches, triforium and clerestory.

As in the Parthenon, the base is an essential feature, and this is common to all ecclesiastical work on the exterior and to the columns of the interior.

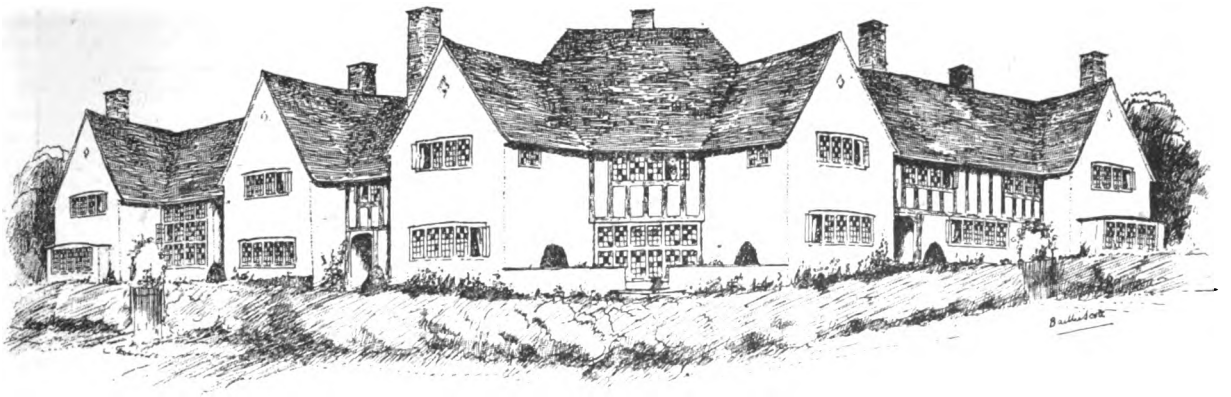
The dominant feature of the chapel in a subordinate way is the nave arches, but more conspicuously the crossing arches and the vaulting which unites all parts of the interior. Other dominating parts in Pointed architecture are the spire, as at Salisbury, and the towers at Gloucester, Hereford and Worcester. Those at Canterbury and Lincoln, magnificent as they are, have their value lessened by the competition between them and the towers at the west ends of the cathedrals.

As a painter has one chief light or incident in his picture, so the architect should have in his Gothic composition some dominating centre, such as a spire or tower, or other commanding element. Its counterpart in Classic is the column, or tower, or dome. We notice how interestingly the pilaster redeems Sir Walter Scott's house in Castle Street from the commonplace; the column also has this effect in the house of Crosbie, in St. Andrew Square, the reputed original of Pleydell in "Guy Mannering," although the law of three has not been satisfactorily observed, inasmuch as the lower division is too shallow for the attic storey. The absence of a leading part is noticeable in some of the three-storey work at the Louvre, at a cloister in Venice, and the Colosseum at Rome.

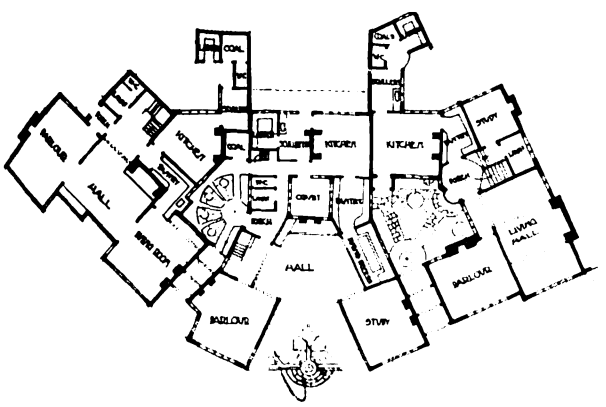
Symmetry is an important element in good architecture in certain buildings. It occurs in all our banks and insurance offices; the Bank of Scotland is notable for that and good grouping; the various asylums with which Edinburgh is so richly endowed exemplify it; Fettes College and the High School cannot be overlooked in this respect.

Of course, when an important building occurs at the corner of a street, picturesqueness rather than symmetry should come into play, as in the excellent Prudential offices in St. Andrew Square. We see how symmetry would be out of place in the case of such a stately front as that of the Commercial Bank if a street were cut through at one end and it so became a corner building.

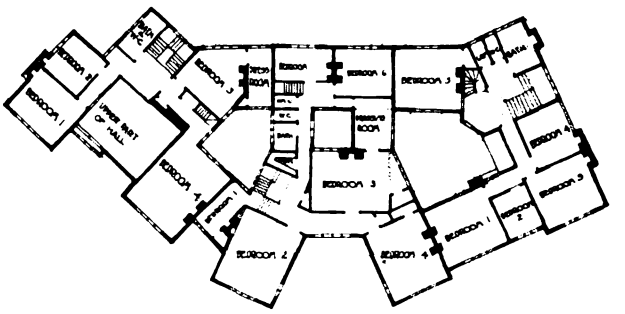
It is understood that the west front of Holyrood Chapel was symmetrical, having two towers before the erection of the Palace demanded the removal of the south-west tower; but the completed front could not be held as a good piece of composition. Like Wells Cathedral, its towers were outside the main structure, and they must have made the front ungainly. Wells was, however, much better proportioned, having its towers higher than those of Holyrood. A domed villa design of Palladio's with quadrant wings, shown on the screen, was explained to be of the old uncomfortable style of formal house, and thus a less symmetrical and ambitious house would have been more comfortable to live in.



Dignity is another essential in architecture; even the smallest building may have some dignity about it, although it is most satisfactorily attained in a large building. It is an attribute of the Parthenon and of the Royal Institution also, which is two-thirds the scale of its original. The great windows of some of our cathedrals excel in this respect, such as those of Gloucester and Carlisle. I shall never forget the effect of Carlisle east window on a summer morning at six o'clock when the sun was shining brightly upon it; the impression made by its greatness and beauty remain a pleasant memory. The great internal arches and vaults of the French cathedrals and of Cologne, the towers of Durham and the central spire of Truro have all elements of dignity.



There is great dignity in the portal arches of Lincoln and Peterborough, but that is gained at the expense of other excellent qualities. They, for one thing, formed no structural part of the building, but were additions to the group by some persons of strong individuality, and we are very grateful to them for so great a departure from precedent, as the result has been much lovely work, though at the cost of the concealment of the tower bases at Lincoln.



Rhythm is important—that is, the regular recurrence of certain portions of a design, such as the flank columns of the Parthenon. We have only to imagine the omission of one of these columns or their irregular spacing to show how this attribute might be lost. The sequence of buttresses in Pointed architecture, the continuous arcading of an interior, or the band of arcading at the summit of the Lincoln porch or the base of the Lichfield west front window, or on a smaller scale the row of graceful Decorated windows in the hall of Bothwell Castle, all show the value of this quality. We may add the repetition of parts in either of the charming upper storeys of the Life Association of Scotland's building.

Simplicity should be kept strictly in view—that is to say, nothing should be put decoratively on a building for which a plain reason cannot be given. There ought to be no "art for art's sake." We can understand why the capital of a column should be floriated, but to decorate the lower part, as is done in Indian architecture and in the Temple of Diana at Ephesus, is not a sign of wisdom. The cornice

HOUSES IN MEADWAY, HAMPSTEAD GARDEN SUBURB.
THE GARDEN SUBURB DEVELOPMENT CO., LTD,
M. H. BAILLIE SCOTT, Architect.

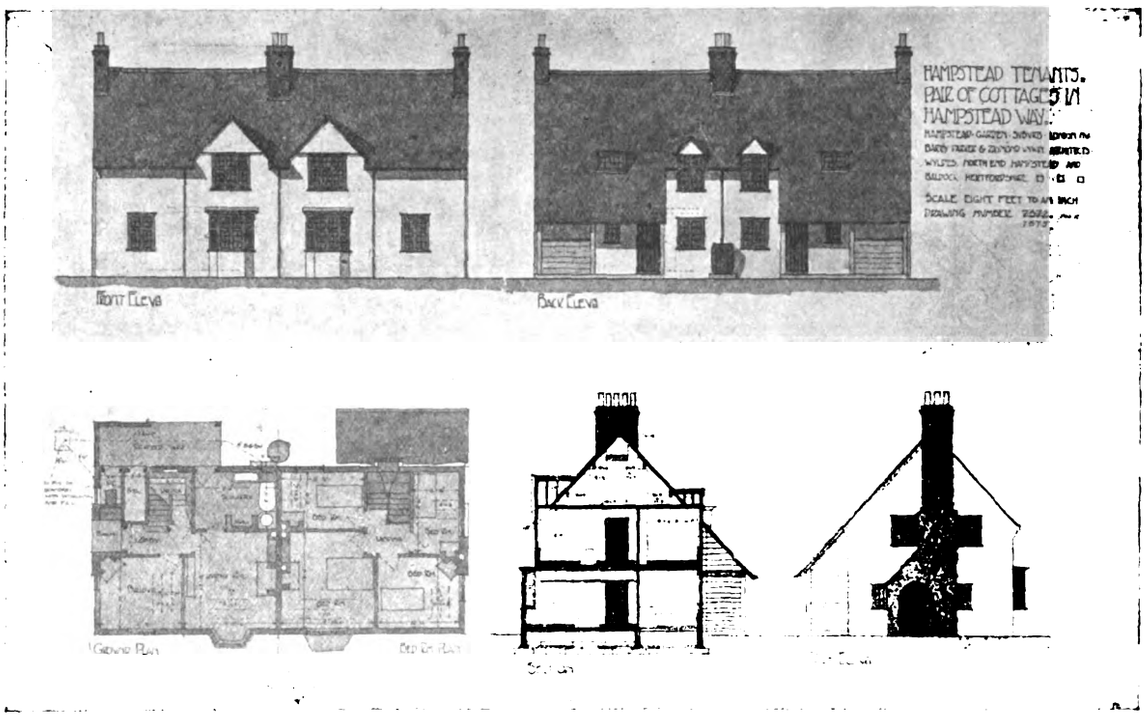
of the Parthenon is consistently simple, but that of the exuberantly decorated one of Jupiter Tonans shows very little consideration for this quality.

Expression, or the impartation of the architect's personality, is a valuable part of architecture. We judge of a tree by its fruits, of a man by his works. It gives interesting variety to architecture when the architect, discarding precedent, puts himself into his design. He may be refined or vigorous, practical or æsthetic in temperament, or happily he may combine, as some have done, the best of these qualities together. Peterborough and Lincoln fronts are, as has been remarked, individual conceptions, although in aiming at one thing the designers have failed in another, but they have certainly avoided the trodden path and the commonplace.

A similar remark may be made concerning Holyrood front, but if one may be allowed to criticise—in these days when everything has to account for itself—we might say that the tower should have been loftier if the front was not to be squat, that its angles should have buttresses and not been tamely shafted, the lower storey having a window and the upper one of belfry character, the intermediate stages having smaller lights, the first-storey arcading omitted; the aisles should have had an end window, and the abutment of the nave arcade strengthened by an external buttress. Of course the reply to these suggestions may be that all the individuality of the front would be gone, and the force of this objection may be frankly admitted. Lichfield seems overdone in the matter of arcading, which shows the ostentatious personality of the designer,; if he had omitted some of the turret arcading he would have had the advantage of contrast, much to the enhancement of the rest.

The picturesque is largely noticeable in much of our great architecture, in Worms, Mayence and Peterborough, and furnishes an invaluable compensation for the loss of dignity which pertains to more formally designed buildings. But this is too wide a subject to be treated of at this time, as it involves the study of Scottish and English Domestic, French and Italian Renaissance, and so forth.

Function is of the first consequence, as we may at once understand by comparing a hospital such as that of Dundee, built half a century ago, with that in our city. Schools should express their purpose externally by showing that they have abundance of light and ventilation. Banks and insurance offices in Edinburgh are very happy in this respect by their suggestion of wealth within and security on the exterior, with a due amount of welcome suggested by their portals. Under this head should be considered the question how far we are justified in using the Mediæval form of church, which was originally designed to suit a processional and spectacular ritual in which the congregation took little part and where acoustics were a secondary consideration, to the need nowadays for good auditoria, where the preacher may be seen and heard. At the same time we cannot afford to forget the hold which so beautiful a phase of Pointed architecture, full of symbolism and hallowed by many fragrant memories, has on the Anglican Church, which has done so much to foster the highest class of ecclesiastical architecture, and which is the only evangelical body able to make full use of churches which resemble the Mediæval foundation.



Under this head three Edinburgh monuments may be referred to—Sir Walter Scott's monument in Prince's Street, Dugald Stewart's and Burns's on the Calton Hill. Scott's, being Gothic, was in harmony with the character of his literary work. Stewart's, after the Choragic Monument of Lysicrates at Athens, is appropriate, inasmuch as his professorial works were related to Greek philosophy; but Burns's, modelled after the Temple at Tivoli, beautiful though it is, ought to have been more domestic in character and imbued with Scottish sentiment. The St. Bernard's Well is an excellent example of consonance with its purpose.

Grace we must not overlook, the more so as at the present time it is so common to design domes and turrets and buttress gables with a severity which will provoke a reaction in time, for this is a kind of simplicity due probably more to a desire for novelty than the application of any true æsthetic principle. The Parthenon, simple though it seems to be, was gracious in its roof terminals and acroteria. Salisbury spire is distinguished for grace as well as dignity.

Scale is exceedingly important, both in reference to the magnitude of the building in relation to its surroundings and the size of the detailed parts in comparison with the whole. There is a golden rule to be followed in this, for either a building may be so small as to be toy-like, wanting in dignity, or so big as to be clumsy and overpowering. The Bank of Scotland head office, to take one instance of several, is a successful example of attention to this. How easily the effect in the Old Town, as viewed from Prince's Street, might have been spoilt through inattention to this. The fine façade of the county buildings lately removed was an illustration of disproportion to the neighbouring buildings of St. Giles's Cathedral and Parliament Square. It is better away for this reason, and happily there is still another fine and better example of the same phase of Greek Ionic in the Surgeons' Hall, Nicolson Street. But it is to be regretted that the portico was not re-erected at one of the public parks, or put against the Calton Hill in the same way as one of the monuments at Athens.

It is perhaps well also that the National Monument was never finished. Had it been begun on a scale of three-

Digitized by Google

fourths the original model it would have been more in scale with the Calton Hill, and the money devoted to its erection would then have gone further.

The dome and spire were finally referred to as the two greatest conceptions in architecture, the one all-embracing, altruistic, an echo of the expanse above; the other, heaven-aspiring and suggestive of another world.

LONDON MUNICIPAL HEAT SUPPLY.

By ALFRED E. WHEELER, C.E.

(Concluded from last week.)

FOR convenience of centralisation each Borough would be divided up into heating districts, each district having a central generating station, with feeder mains radiating from same, as described under the section "Distribution of Heat." The number of stations would depend upon the area of distribution decided upon, the division suggested being approximately one to each square mile. The following table shows the various London districts with the area of each in square miles, together with the total B.T.U. required per hour, number of stations, and number of boilers to each:—

Borough.	Population.	Millions B.T.U.	Area Square Miles.	Number of Stations.	Boilers per Station.	Total Boilers.
Battersea	168,907	563	3·40	3	10	30
Bermondsey	145,760	484	2·36	3	9	27
Bethnal Green	129,680	428	1·18	2	12	24
Camberwell	239,339	863	6·95	5	10	50
Chelsea	78,842	263	1·02	1	14	14
City of London	—	338	1·05	2	9	18
Deptford	160,398	535	2·46	3	10	30
Finsbury	121,463	405	0·92	2	11	22
Fulham	187,289	624	2·66	3	12	36
Greenwich	95,770	319	6·00	2	9	18
Hackney	229,272	763	5·16	5	8	40
Hammersmith	112,239	373	3·58	3	7	21
Hampstead	87,942	292	3·52	2	8	16
Holborn	59,405	195	0·64	1	10	10
Islington	334,991	1,115	4·86	5	12	60
Kensington	147,628	492	3·42	3	9	27
Lambeth	301,895	1,005	6·42	6	9	54
Lewisham	127,495	425	10·95	2	12	24
Paddington	143,976	478	2·19	3	9	27
Poplar	168,822	563	3·64	3	10	30
St. Marylebone	133,301	443	2·34	2	12	24
St. Pancras	235,517	782	4·17	4	10	40
Shoreditch	198,637	660	1·02	2	18	36
Southwark	206,180	685	1·75	2	19	38
Stepney	298,000	993	2·76	4	14	56
Stoke Newington	51,247	171	1·36	1	9	9
Wandsworth	232,032	772	14·25	4	10	40
Westminster	188,011	625	4·00	4	9	36
Woolwich	117,178	356	12·95	2	10	20
Total	4,721,216	16,010	116·98	84	—	877

A careful examination of this table will again demonstrate to advocates of the electrical method of distribution the unsuitability of that method. It is unnecessary to remind them that unlimited supplies of heat cannot be drawn from the present electric supply mains and generating plant without considerable extensions, and that the present plant and existing cables have their limits.

If a public supply of heat is determined upon, under whatever system adopted for the distribution of same, a complete new plant must inevitably be laid down. From the above table it will be seen that by the system suggested, the requirements would call for 877 boilers and 84 generating stations. This represents about 1.5 times the present number of boilers contained in all the electric lighting stations in London. To transmit the same heat electrically a comparison of previous figures will show that the addition of about 4,300 boilers to the present combined plant of some 580 boilers would be necessary for heat alone, assuming that the bulk of the heating might be done as a day load, and the lighting as a night load on the same plant.

And now I will proceed to a brief description of the plant comprised in one generating station which would be representative of them all. The boilers would be of the tubular type, with the usual steam and mud drums reduced to mere headers for the tubes, and provided with pipe connections. The tubes of the boilers would contain about 5,200 square feet of heating surface, and the fire grate surface would be in the ratio of one to ninety to the heating surface. The boiler would be provided with forced draught arranged to burn smokelessly not less than 30 lbs. of coal per square foot of grate per hour. The whole battery of boilers would be coupled together in the method known electrically as "parallel," and each boiler being so "bye-passed" that any one or more boilers could be "cut in" or "cut out" of the heating circuit, or isolated for cleaning or repairs if and when required.

The "flow" main leading away from the boilers would be connected to the suction connection of a high efficiency triple expansion, or compound pumping engine constructed for use with superheated steam, the steam for the steam pumps being generated in a separate steam boiler.

As the temperature of the circulating heat distributing water is somewhat high, the gases leaving the boilers would necessarily be of a high temperature. Economisers of the well-known tubular pattern would be erected in the main flues in which the high temperature flue gases would heat the feed water for the steam boilers to the point of evaporation, the duty of the steam boiler then merely being to evaporate the water into steam, which, passing through a super-heater situated in the path of the hot gases from the steam boiler, would impart some 100 degrees of superheat to the steam. The exhaust steam from the feed pumps and from the circulating pumps would be condensed in a good open type feed

Digitized by Google

water heater, which would heat the feed water to near 212 degrees before passing on to the economisers. Such an arrangement it is calculated would make for the highest degree of thermal efficiency obtainable.

The pumps would be installed in duplicate and also connected in parallel, being bye-passed similarly to the boilers. The proportions of the cylinders, and the arrangements of the connections would be such that the pumps could by a suitable arrangement of valves and governors be used as pressure pumps or circulating pumps, as required. The pumps would be fixed in a distributing room adjacent to the boiler house, in which would also be fixed a pair of multiple circulation distributors, one of which would be connected to the delivery main from the pumps, the other collecting up the return mains and passing the returning water on to the boilers for re-heating.

A recording thermometer would be fixed upon each of the multiple distributors, and one of the principal duties of the engineer in charge of the station would be to maintain the 100 degree temperature head constant between the two distributors. This could be achieved in a variety of ways, notably by the regulation of the pumps, by the draught fans and stoking.

(3) *System of Distribution.*

The difference between any arrangement of distribution for a municipality as compared with that for a single institution, would be in the fact that the demand would never be constant at any specific time. Every effort therefore should be made in arranging the distributing system so that it may be as nearly as possible self-equalising.

From the multiple distributors already referred to in the distributing room would be taken flanged steel feeder mains through trenches constructed in the streets. Upon each out-going feeder main would be fixed a relief valve loaded to 275 lbs per square inch. At various points on the feeders, supply and return mains would be taken off, the combined sectional area of which being equal in cross-sectional area to the feeder main from which they are taken. From the latter supply mains, the services would be taken to the consumers' units. No cross-connection would exist between the supply and return mains except through the consumers' connections, and similarly no connection would exist between the flow and return feeder mains except through the supply and return mains by way of the consumer connections referred to. This arrangement of distribution would have the effect of equalising the delivery in each set of feeders. The velocity of water through the feeders and system generally would be about 10 feet per second, which figure is conditional upon a constant total cross sectional area (or corresponding friction head) being maintained. As the flow would tend to favour the circuit in which frictional resistance is least, the velocity would rise in this circuit until the frictional resistance (which it should be remembered increases about V^2), increased sufficiently to equalise the flow with the other circuits automatically.

The question of the total area of the consumer connections also demands judgment rather than calculation. It is, of course, improbable that all heat consuming devices would be open at the same time, but provision must be made for such a contingency. It is therefore suggested that a suitable number of connections should equal in area about 1.3 x sectional area of supply main.

The standard heating device would consist of a small battery of specially designed heating surface. These would be standardised at a pre-determined rated duty, and would be described by their capacity in B.T.U. The connections from the supply main to each heat consuming unit would be of such a size as to deliver to the heating unit a sufficient quantity of water per hour at standard velocity to contain the specified number of B.T.U. under the particular duty in heating apparatus or hot water supply for which the heating unit would be rated, *i.e.*, each heater would be capable of 50,000 B.T.U. per hour, as a maximum under heating or hot water service conditions as may be required. Each consumer's connection would be provided with a meter in circuit every 100 gallons, recorded upon the meter dial being the equivalent of 10,000 B.T.U., as described in the section, "Payment for Supplies." The amount of heat could be varied as required by merely regulating the quantity of water passing the meter by the simple process of turning the valve.

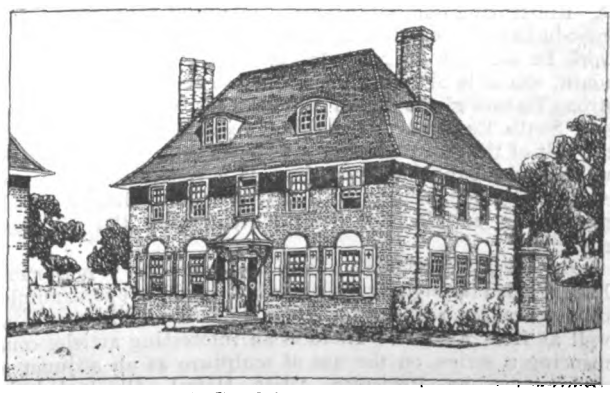
The feeders and supply mains would be laid in wood-lined trenches and packed with silicate cotton, as an insulator. The heat loss under these precautions would be negligeable. To provide for expansion suitable sliding expansion joints with packed glands and guard bolts would be fixed at frequent intervals in suitable access chambers, the pipes being firmly anchored in mid-position between joints to ensure equal movement on each joint.

As regards the sizes of the mains, each main should be standardised so that the friction head on each main should be as nearly as possible the same to ensure even flow throughout all circuits.

As a guide to the sizes, it may be mentioned that a 12-inch diameter feeder main would carry 4,580 standard heat consuming units, and a 3-inch supply main 284 such units, the connection to each unit being about ¼-inch diameter.

(4) *Payment for Supplies.*

Not the least detail of the municipal heat supply scheme would be the question of the method of measurement of, and payment for supplies on a basis at once satisfactory to the consumer, and remunerative to the vendors.



It is unnecessary to go into details of the apportionment of funds at present. I will, therefore, merely indicate the method of payment for heat supplies, and suggest a figure which should certainly cover all expenses of administration and depreciation of plant, leaving a substantial surplus for devotion to other necessary purposes.

To formulate a suitable unit of measurement is not a light task. The B.T.U., of course, is an unpractical quantity as a commercial unit, being far too small for anything but theoretical calculations. The practical unit of heat, which I shall propose to designate a "heat unit," would be the equivalent of 100,000 B.T.U., a quantity which lends itself in a strikingly useful manner for our purpose, as the following will show.

A standardised heat consuming battery having a maximum capacity of 50,000 B.T.U. per hour has been suggested. This, it will be seen, is equal to 0.5 "heat units" per hour at its full capacity, *i.e.*, the heat consumption of two of these batteries would be one "heat unit" at the maximum delivery through it of 100 gallons per hour. This quantity could be reduced when less heat is required by regulating the stop valve to the desired delivery.

Now let us see what the actual net value of our "heat unit" would be. Each boiler would be equal to a duty of about 18,000,000 B.T.U. per hour, and would be constructed to burn with forced draught 30 lbs. of coal per square foot per hour. The total B.T.U. utilised per 1 lb. of coal for heating purposes would be about 10,440 B.T.U., or equal to a thermal efficiency of 72 per cent. With coal at an average price of 20*s.* per ton, our "heat unit" would cost 1.026*d.* If the "heat unit" is charged out to consumers at 2*d.*, there is no doubt that the 98 per cent. surplus would considerably more than cover all the charges referred to, and at the same time remove all suspicion of bias in comparisons of cost with gas and electric heating. The annual earnings of Hampstead, for example, with its sixteen boilers, would thus run out at about 39,000*l.*, working at an eighteen-hour day with an average 50 per cent. load for the year after all coal had been paid for. The earnings of each boiler are thus seen to be about 2,400*l.* per annum, showing a gross estimated annual earning capacity for London of 2,100,000*l.* after deducting fuel cost. The suggested 2*d.* rate could no doubt be reduced to a much lower figure in the hands of expert financiers, and a surplus might even be obtained to be applied to the relief of the rates.

Coming to the question of measurement, each consumer's connection would be provided with a meter in circuit; the dial of the meter instead of being marked in "gallons," as is usual, would be marked "heat units," otherwise it would

HOUSE NEAR THE HEATH EXTENSION FOR THE GARDEN SUBURB DEVELOPMENT COMPANY (HAMPSTEAD) LIMITED.

Messrs. MICHAEL BUNNEY & C. C. MAKINS, Architects

Digitized by Google

be unaltered. As a "heat unit" would be the equivalent of 100,000 B.T.U., the exact alteration in the marking of the dial would be as follows:—

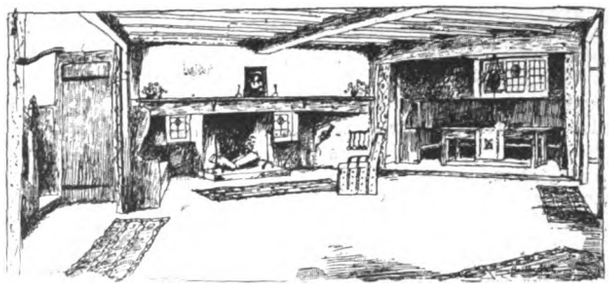
The "hundreds" dial would be marked "heat units." The "tens" and "units" dials would be marked quantities below unity. The "thousands" and "ten thousands" dials, quantities above unity.

The meter on being installed would be proportioned to pass an hourly quantity of water at standard velocity, proportionate to the capacity of the heating battery installed. For example, each pair of "half unit" heaters would require as a maximum 100 gallons per hour, the meter would thus be termed a "1 unit" meter, and would be the minimum size.

With the flow-equalising method of connections already described, and the careful attention to the recording thermometers at the generating station, no difficulty whatever should be experienced in maintaining the 100 degree temperature head, and the amount of heat chargeable to the consumer would thus bo determined with a great degree of accuracy.

How would the cost of house heating by means of municipal supply compare with heating by gas or by electricity? Let us see. A hypothetical case may be taken of a house containing 320 square feet of radiation in eight radiators of 40 square feet each, with hot water radiation. Each square foot will give out under average conditions about 200 B.T.U. per hour, and allowing 33 per cent. for lost radiation from pipe connections, &c., as before, the total hourly consumption of heat would be 85,300 B.T.U. (= .85 heat units). In a week of eighty-four hours the heat consumption would total 71.65 "heat units," which at 2*d*. per unit costs 12*s*. To do the same work with gas radiators (making due reduction in the heating surface for the greater heating power per square foot) the eight radiators would consume 14 cubic feet per radiator per hour or 9,420 cubic feet for the eight radiators per week of eighty-four hours, the cost at 3*s*. per 1,000 cubic feet being 1*l*. 8*s*. 3*d*. An electrically heated plant would consume one Board of Trade unit per hour per radiator for an equal duty. The cost of an eighty-four-hour week for the eight radiators would thus be 2*l*. 16*s*. It is thus evident that at current prices the cost of heating by gas would be 135 per cent., and by electricity 366 per cent. more than by municipal supply. As to how the poorer classes would be affected by the change, it may be stated that with two radiators in constant use, having a total surface of 40 square feet or its heat equivalent, the weekly cost for heat for sixteen hours per day would be a fraction under 1*s*. 6*d*.

The question may arise, How would the new system affect existing heating plants? The answer is that it would affect them not at all. A special new heater would be installed to take the place of the boiler or calorifier, and whether the system were a steam or a hot water one its heat supplies could be drawn with equal facility from the municipal supply mains.



As a concluding remark, it only remains to be said that the writer has no desire to advocate any revolutionary changes, but merely to demonstrate that a scheme of heat supply for London, though ambitious, is not an impossibility and a worthy achievement of the twentieth century.

OUR CONTEMPORARIES FROM OVER-SEAS.

THE *American Architect* in its last two issues has been illustrating domestic architecture in the Southern States, introducing the series with an account of both old and new work in the city of Augusta, Georgia. Naturally in the south, shade is of importance, and we find the verandah a strong feature of the design of houses for Georgia, Alabama, and South Carolina. One thing we note with pleasure is the cult of the roof; whether the houses belong to the Italian villa or the bungalow type there is a goodly projection of eaves and verge, which, with the verandahs already noted, makes for satisfactory design even with the simplest elements.

Der Architekt shows us how the "new art" movement has extended throughout the whole of inland Europe, examples being given from Bucharest, from Luhacovic in Bohemia, as well as from Austria. There is an interesting article, commencing a series, on the use of sculpture as an adjunct of architecture by Professor Adolf Hölzel, illustrated by examples from both old and modern work.

A Construcçao Moderna illustrates a model of one of the premiated designs—that by Germano Salles, of Paris—in the recent competition for a monument commemorative of the Peninsular War, a remarkably expressive and powerful composition. In this number we are also interested to see an article on municipal housing in England and Germany, apropos of our Town-Planning Bill and with reference to the garden cities of Letchworth, Hampstead, Port Sunlight and Bournville, as well as the German development of Düsseldorf, Frankfort, Berlin, Munich and Strasburg.

HOUSE IN MEADWAY FOR THE GARDEN SUBURB DEVELOPMENT COMPANY (HAMPSTEAD), LTD.
M. H. BAILLIE SCOTT, Architect.

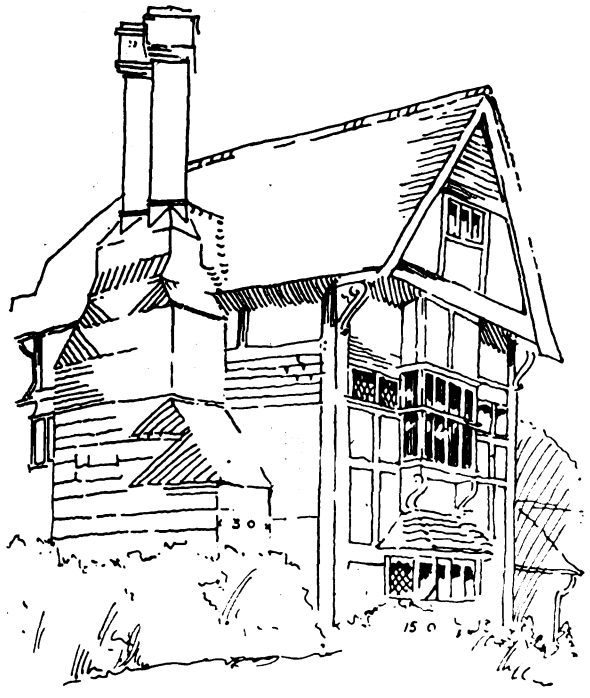
Deutsche Bauzeitung gives us views of the extensions and additions to the Schloss Vollrads in Rheingau, of which Herr Philip Kahm, of Eltville-on-Rhine, is the architect, who, without sacrificing individuality and originality, has preserved the character and feeling of the old work in his own designs.

La Construction Moderne honours our modern work with an article and full series of illustrations of the village of Bournville and its domestic architecture, giving full appreciation to the work of Mr. W. A. Harvey as the creative collaborator in the scheme conceived and initiated by Mr. George Cadbury.

GENERAL.

Mold Church, one of the most historic edifices in North Wales, is to be restored at a cost of about 5,000*l*.

The Chancellor of Winchester has granted an application for a faculty to demolish the old parish church of Bishopstoke, against which there had been opposition on the part of a number of parishioners.



The Church of Kirkdale, near Kirby Moorside, is to be restored. The original building dates back some twelve hundred years, and the present edifice has two fine Saxon doorways. Over the south doorway is a quaint sundial, 7 feet long and 2 feet wide, and around it are Saxon inscriptions, cut in well-defined characters, dating from 1060.

Mr. John Tweed has received from the Clive Memorial Committee the commission for the bronze statue of Lord Clive to be erected on the steps at the end of Charles Street, Whitehall, and the marble statue to be placed in the Victoria Memorial Hall at Calcutta. The new stairway at the end of Charles Street, overlooking St. James's Park, will be so adapted as to provide a pedestal and base for the statue.

The Corner Stone of the new St. Saviour's Church House and Church Men's Club was laid by the Bishop of Kensington on Saturday, June 12. The building, which is in late fifteenth-century Gothic, fronts on the Grove Road, Ealing. A central feature of the design is the large doubled-arched entrance and passage way placed between the clergy house and the men's club, leading to the church enclosure. The gabled roof of the chapel rises on the third floor above the entrance. There is convenient accommodation for three clergy, and a fourth bedroom for visitors and a large common room for general purposes. Except for communication through the kitchen and by a single passage on the first floor, the servants' wing is entirely separated from the main building. Nearly the whole of the roof space is converted into a roof garden. The accommodation of the club consists of a billiard-room, a large reading-room, writing and committee-rooms, with caretaker's rooms on the third floor. The total cost of the Church House and club will be about 4,500*l*. The architect is Geo. H. Fellowes Prynne, F.R.I.B.A., of Westminster, from whose designs St. Saviour's Church was built some nine years ago, and the builder is Mr. W. J. Dickens, of Ealing.

The Southwell Diocesan Council at their last meeting considered a proposal to appoint a diocesan architect, to whom all plans and specifications relating to the building or restoration of churches, rectories, vicarages, parish buildings and schools should be submitted before any work was begun. A resolution was proposed that such appointment should be made. This was not seconded and the matter dropped.

AT PENSHURST, KENT.
From a Sketch by BANISTER FLETCHER.

THE WEEK.

LONDON'S Fire Brigade is almost entirely manned by sailors, and it has of late been the custom, apparently, to consider that a naval officer is the most suitable individual to command the Brigade; but the Special Commission of the British Fire Prevention Committee seems to have learnt, as one of its lessons on its latest tour, that our practice is open to question; for in Berlin there has been a most marked improvement in the service since it has been officered by civil engineers and surveyors. There is, however, this to be said—that in Berlin these officers have almost, if not quite, all passed through the army and have learnt what discipline, command, and organisation mean in the handling of men to fight a common foe.

To the ordinary householder sanitation means drains and drains only, but Professor C. E. A. WINSLOW, we learn from the *Engineering Record*, in a recent discussion before the Sanitary Section of the Boston Society of Civil Engineers, put forward the view that a person inhaling drain air for twenty-four hours would ingest fewer intestinal bacteria than in drinking a quart of New York water. The Professor based his view on an examination of 200 samples of air from house drains, soil pipes, vents, and wastes. So it seems we have been riding to death the importance of plumbing and drainage work, and forgetting the need for pure water, pure milk, and other desiderata.

THE fine collection of Wedgwood ware that Mr. ISAAC FALCKE has presented to the British Museum is particularly notable for the copy of the famous Barberini vase, a work that occupied WEDGWOOD for three years, and of which only sixteen specimens are known to be extant. The original vase now, though broken and repaired, is in the British Museum, and was discovered in a sarcophagus bearing an inscription to the memory of the Emperor ALEXANDER SEVERUS and his mother, JULIA MAMMÆA.

IT was foretold some years ago by the late Professor KERR, at an Institute meeting, that architecture would descend from the level of a profession to that of commercial business, and it seems we are getting on apace in that descent, for there has recently been registered a limited liability company whose objects are "to acquire and deal with lands, woods, building estates, and waterways in the United Kingdom and elsewhere, and to carry on the business of land, house, and estate agents and dealers, builders, surveyors, *architects*, draughtsmen, &c." In face of such facts can it be doubted that the time is ripe for registration?

THE unveiling on Friday last of the monument at Reading "to the memory of HENRY BEAUCLERC, King of England, who founded Reading Abbey on June 18, 1121, and was buried before its high altar on January 4, 1136," belated as it is, even now is due entirely to the generosity of Dr. JAMIESON B. HURRY, M.A., who has thus still further increased the debt of gratitude owing to him by the people of Reading for his great work on the history of the Cluniac abbey which first gave their town its start as a township of any importance. The memorial takes the form of a cross, somewhat of Celtic form, constructed in Cornish granite, and was designed by Mr. W. RAVENSCROFT, F.S.A., of the firm of RAVENSCROFT, SON & MORRIS, architects.

THE celebration of the successful accomplishment by the Bishop of BATH and WELLS of his self-imposed task of rescuing the remains of the abbey of Glastonbury is an occasion for congratulation. Glastonbury is so closely connected with the history of Western England that its demolition would have been a national calamity, now averted by the vesting in the diocesan trustees of the See of Bath and Wells of the property of the abbey estate. More remains to be done in the work of restoration—or rather preservation—for Mr. W. D. CARÖE, to whose hands the operations are entrusted, is a conservative restorer, and with the object of raising funds for this purpose it has been decided to relet the estate for a further term of five years.

THE restoration of the so-called "Dutch House" preserves to Bristol a quaint and picturesque specimen of domestic architecture, and has been judiciously carried out by Mr. W. S. SKINNER. Whether or no there is any truth in the tradition that the Dutch House was brought over piecemeal from Holland—and we doubt the truth of the story—Bristol is fortunate in having preserved for its delight and instruction a characteristic piece of seventeenth-century domestic architecture. The house is now the property of the Town Council, and it seems that it was due to the influence exerted by the Bristol and Gloucestershire Archæological Society, the Bristol Society of Architects, the Bristol Kyrle Society, and the Society of Antiquaries that the Town Council were persuaded by a small majority to acquiesce in the preservation of this historic monument.

IN view of the durability of such structures as the Bristol "Dutch House," it is curious to note that at the Warwick Assizes one Coventry builder was mulcted in damages for slander against another Coventry builder, of which the substance was that oak beams had been used in the foundations of certain houses. The essence of the slander seems to have been that the use of the oak beams was presumed to be contrary to the by-laws of Coventry, and hence an improper and jerry-builder's method of construction. The curious part of the case was that anyone should suppose that oak beams—provided, of course, they were sound at first—would not last longer than steel joists.

WELLS Cathedral and "Boston Stump" have, during the past week, been celebrating—the former the millenary of the bishopric of Wells, the latter the sexcentenary of the laying of the foundations of the church of St. Botolph. One cannot but admire the persistency of the clergy in utilising pageants and centenaries to revive sympathy in the work of the Church; and whether the interest in the past that such functions usefully arouse results in adherence to the present order of things or not, the contemplation of the art and faith of our ancestors cannot be altogether without good.

COMPETITION FOR MIDDLESBROUGH PUBLIC LIBRARY.

WE understand that those competitors who feel that the departures from the conditions of this competition, alleged by them to be found in the design of Messrs. RUSSELL & COOPER, are of so exceptionally grave a character as to justify their indignation at the unfair treatment they think they have received, have, as we suggested last week was their only course, addressed their remonstrance to the President of the Royal Institute of British Architects, and have tabulated their grounds of dissatisfaction as follows:—

Instructions. (Issued to Architects.)	Queries. (Asked by Competing Architects.)	Replies. (Sent to Competing Architects by Town Clerk.)	Selected Design.
1. The general lending and reference libraries are to be placed in the northern part of the block adjoining the dwelling-houses in Dunning Street. (Paragraph 3, page 4.)	100. Are the positions of lending library and news room absolutely unalterable?	100. Yes.	Lending and reference libraries separated about 37 feet from houses in Dunning Street by boys' and girls' reading rooms.
	106. Are the positions for the various rooms to be absolutely adhered to?	106. Paragraphs 3 and 4, page 4 of Instructions, must be adhered to.	
	72. Must the lending library and news room occupy the relative positions prescribed for them?	72. Yes.	
2. Secondary entrance from Grange Road East. (Paragraph 3.)	75. Whether entirely distinct entrances from the two roads, Dunning Street and Grange Road East, are desired for the lending library, &c., and news room?	75. See 2nd and 3rd paragraphs on page 4 of the Instructions issued to architects.	No secondary entrance in Grange Road, but one provided in Dunning Street.
	84. Should there be two entrances from Grange Road, viz. one for the general news room and one for secondary entrance to lending and reference libraries?	84. Yes: but secondary entrance not necessarily to lending and reference libraries.	
3. Boys' and girls' reading rooms to be divided by glazed partition running from the service counter.			Two counters and two partitions provided.
4. Juvenile book store to have steel gallery.	49. Would a gallery of sufficient width for one row of wall-cases be enough in the juvenile book store?	49. Yes.	None provided.
5. Catalogue room to be on ground floor.	53. May the repairing room be on first floor and separate from receiving and catalogue room?	53. No.	Catalogue room separate from repairing and receiving room and placed on first floor.
6. The general news room to have entrance from Grange Road East.	81. Must the direct communication asked for between Grange Road and Dunning Street be by means of corridor, or would it be sufficient to have a door in the general news room communicating with the main hall and stairs?	81. No communication other than for janitor between news room and other parts of building.	9-feet corridor shown with swing doors communicating between news room and main building.
	80. Should there be access for the public between the general news room and main buildings without going outside the buildings?	80. No.	
7. Patents library and extension lavatory and w.c.'s for male and female staffs, corridors, &c. Area, 1,739 square feet.	92. What is meant by "extension" in connection with the patents library?	92. A room for library extensions when required.	Area provided about 850 square feet. No provision for extension.
8. Furnace, boiler and coke store to be on ground floor.	55. May the repairing room be in the basement?	55. There is no basement, so must be on ground floor as set forth in the Instructions.	Placed in basement.
	61. May the furnace boiler and coke store be in the basement, as there is no basement mentioned in conditions?	61. No basement provided for.	
9. The general reference library should be entirely lighted from the roof direct: there must be no glass ceiling lights.	66. By the lighting of the general reference library from the roof direct, it is presumed that either skylights, a lantern light or dormer windows are suggested, and that the prohibition of glass ceiling lights refers to false lights below a skylight?	66. Refers to false lights.	Side windows provided. Not lighted from roof direct at all.
	69. Lighting of reference library—are skylights wanted and no side windows?	69. See Instructions.

HAMPSTEAD GARDEN SUBURB.

PROPOSED GROUP OF HOUSES.—Messrs. BARRY PARKER & RAYMOND UNWIN, Architects.

ARCHITECTURAL COPYRIGHT.

ARTISTIC copyright as affecting architects is a matter of very great importance, not only to architects, but also to architecture. The unauthorised copying of good designs is largely prevalent, and is frequently accompanied by such mutilation that the artistic character of the original is lost; hence the art of architecture suffers, the public taste is degraded by a mistaken reverence for what is supposed to be, but is not, the work of an artist; further travesties follow the first inadequate plagiarism, and both the representation of architecture and its appreciation fall further into the slough. Then, as regards architects, not only is the author deprived of the reward due to him for his original conception, but his reputation suffers by the unworthy copies that masquerade as his design.

The right of architects and architecture to participate in the protection proposed to be afforded to artistic productions by the Revised Convention of Berne, signed at Berlin last November, has been ably championed by Mr. JOHN W. SIMPSON before the Committee of the House of Commons appointed to examine and report upon the changes proposed in the law of artistic copyright. Mr. SIMPSON well emphasised the close analogy between the methods by which a work of architecture is produced and those employed in the art of sculpture. He emphasised the position of the architect as an "author," and hence on the same plane as any other author of intellectual property, whether literary or artistic. Objections that might be raised to the protection of an architect's work on the ground of its utilitarian character or its position as a subject of public view and enjoyment, were shown by Mr. SIMPSON to be equally applicable to the works of sculptors.

Mr. SIMPSON's advocacy before the Committee was supported by twenty-three definite complaints from members of the Royal Institute of British Architects, from the President downwards, of legitimate grievances which show most clearly how serious are the disadvantages under which architects labour from the want of protection for their artistic copyright. Thus there cannot be the slightest doubt as to the necessity of such protection.

Nor is there, as Mr. SIMPSON has shown, any question as to the desire of architects in all countries of the Union for legal protection. The International Conferences of Architects at Paris in 1878, 1889, and 1900, at Brussels in 1897, at Madrid in 1904, London in 1906, and Vienna in 1908 have each passed unanimous resolutions to this effect; and similar resolutions have been adopted by the Congresses of the International Association of Art and Letters held at Paris, Madrid, Neuchâtel, Milan, Barcelona, Antwerp, Berne, Monaco, Turin, Liège, Bucharest, Mayence, and elsewhere, from its foundation in 1878 to the present time.

Of the practicability of effective protection to architectural work there can also be no doubt. It has already been done in Denmark, France, and Belgium, and decided cases in these countries were cited by Mr. SIMPSON. The fear that the work of students, with regard to important monuments and public buildings, might be interfered with by the action of copyright, is declared by Mr. SIMPSON to be an error, as anyone would be free to sketch, measure, or otherwise study any work so long as he did not make reproductions of it for his own profit to the injury of the author.

The case, therefore, on behalf of the right of architects to benefit equally with painters and sculptors in the protection of artistic copyright is, we think, fully made out, and Mr. SIMPSON deserves the thanks of all architects for the able way in which he has presented the case, as the representative, with Mr. JOHN BELCHER, R.A., of the Royal Institute of British Architects. We shall be surprised if the claims of architects are not admitted by the Houses of Parliament, and incorporated in the Act which is to give effect to the Revised Convention of Berne. Then we should have an end to the disastrous result under which British architects are groaning of the decision in the leading case of *Gibbon* v. *Pease*.

BRUSSELS INTERNATIONAL AND UNIVERSAL EXHIBITION.

MANUFACTURERS all over the country are beginning to realise and appreciate the extraordinary amount of assistance offered to them by the British Government to enable them to make suitable exhibits at the Brussels International Exhibition next year. The Royal Commission appointed to take charge of the Exhibitions at Brussels in 1910, and at Rome and Turin in 1911, has studied exhaustive reports of executive work in other countries, and has also been at great pains in investigating the methods pursued at previous exhibitions in which Great Britain participated. The result of all this work is shown in the untiring energy now being displayed by the Board of Trade officials in securing the many favourable considerations which should influence the British exhibitor.

The Royal Commission, which is presided over by H.R.H. the Prince of Wales, has its offices in Queen Anne's Chambers, Westminster, and the active official is Mr. U. F. Wintour, Secretary and Commissioner-General and Director of the Exhibitions Branch of the Board of Trade. This branch is to be a permanent office for the consideration of future and revision of past international exhibitions in which Great Britain has been, or will be, concerned.

Every conceivable information required by proposed exhibitors can now be promptly given. Up to the present many instructive circulars and Press paragraph matter have been issued, and the willing interest attracted of chambers

Digitized by Google

of commerce everywhere in the country; while from the chiefs of the great railroads, the steamship companies, and of every other important transport company, hearty assistance in the shape of cut-rates has been assured.

Position of the British Section.

The report of the committee of investigation showed most conclusively the many causes for the disinclination to exhibit and the general lack of enthusiasm in recent years on the part of the British manufacturer for international exhibitions. They complained of lack of organisation, of isolation of exhibits, of unsuitable surroundings, of unwarrantable expense, of the necessity of costly personal supervision, of the decrease in the value of awards, and of several more defects and shortcomings which the Royal Commission will do its best to obviate, curtail, or amend, as is suitable in each case. At Brussels next year the British Government has secured perhaps the most prominent position in all the Exhibition for its section. Hitherto, owing to carelessness or tardiness, Great Britain has seen in nearly every instance all the good positions secured prior to advancing her own claims; this time the British representatives were prompt to seize on a primary choice. The British section amounts to 203,140 square feet, of which 150,640 square feet are in the Industrial Hall and 52,500 square feet in the Machinery Hall. The amount of space covered, and certainly the positions secured, compare most favourably with the allotments to other countries. One great advantage lies in the fact that visitors must pass through the British galleries before reaching the French, German, Italian, American and other national sections, and the old proverb of "first impressions" holds good.

The main gallery running through the British section is 510 feet long by 98 feet wide, and there are four other parallel galleries 56 feet wide, which lend themselves to the formation of attractive courts for the display of the different classes of manufactures. At the end of the main gallery, furthest from the entrance, is a double staircase leading to a bridge which gives access to the French and other foreign sections.

The Isolation of British Exhibits.

In the Machinery Hall the portion allotted to Great Britain occupies the centre of the hall, and has easy access to the electric, steam, water and gas mains, from which power can be obtained for showing all classes of machinery in motion. It is also intersected by three lines of rails which communicate directly with the Belgian State Railway system.

There will be no isolation of British exhibits; all will be shown together appropriately grouped and arranged under the immediate supervision of officials of the Royal Commission. All the exhibitor has to do is to purchase the space he requires and see to the transportation, for which a variety of special facilities have been secured. The principal railway companies, for instance, have agreed to accord a reduction of 50 per cent. on the usual rates for the conveyance of all unsold exhibits returned after the close of the Exhibition.

The Royal Commission officials will undertake the entire handling of the exhibitors' goods within the Exhibition, not only unloading and displaying on the space reserved, but storing all empty packing cases and reloading at close of Exhibition. With the exception of machinery and rolling stock, the exhibits of Great Britain will be grouped so as to form a complete national display of the various manufactures and products; and, with a view to uniformity, the Royal Commission will undertake the entire decoration of the British section and provide all show cases, stands, platforms and screens required by each individual exhibitor without further charge.

The importance of this determination to provide free show cases, &c., can be readily appreciated by quoting a paragraph from the report of the Board of Trade Committee. It seems that other Governments at previous international exhibitions invariably insisted on a general scheme of decoration and uniformity of pattern in show cases. "In the British section," says the report, "no considered plan would as a rule appear to have been adopted in allotting the space to exhibitors of different classes of goods. Artistic pottery has been exhibited side by side with trouser stretchers, scientific instruments have been placed next to the exhibit of a theatrical wig-maker, and glassware of a highly decorative character has been surrounded by pyramids of empty bottles and syphons. In this manner the uneven quality of many of the exhibits has been accentuated and the general effect of the section spoilt. The decoration of the exhibits, moreover, appears to have been left almost entirely to the exhibitors themselves. Each exhibitor has provided his own show case, and has decorated his stand in the manner that pleased him best."

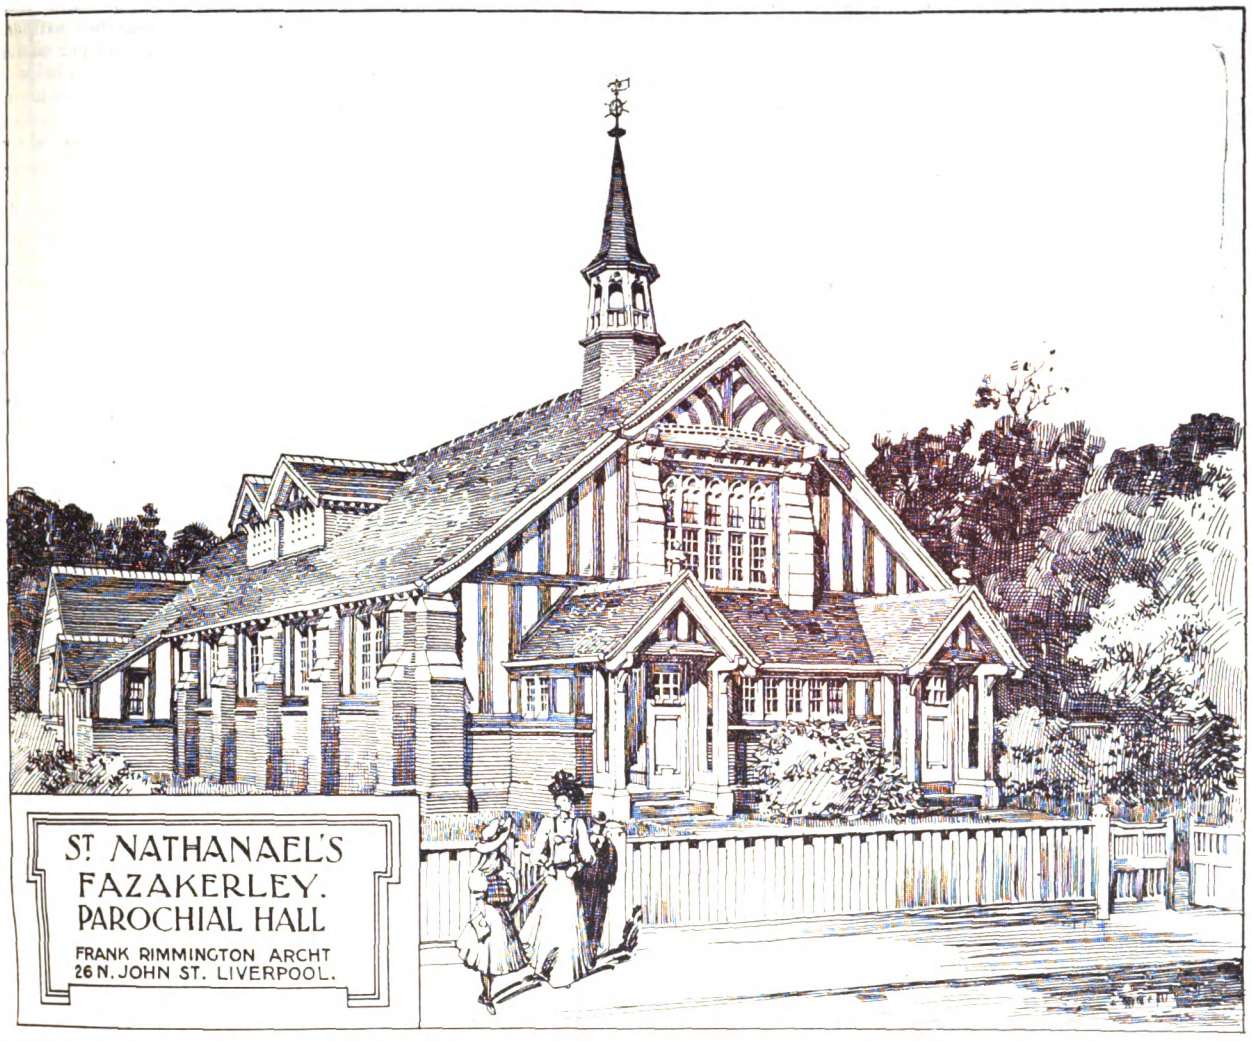
The Scheme of General Decoration.

In order to assist in attaining this desired and most necessary improvement the scheme of decoration and grouping will be carefully explained to intending exhibitors, and every endeavour made to reconcile conflicting interests. The internal fittings and the material used for lining must, of course, be at the expense of the exhibitor; but the attractive and harmonious design of the show cases, it is anticipated, will appeal most favourably alike to exhibitor and spectator.

Every care will be taken to prevent any deprivation of individual character from the exhibits, either by too close proximity or other unharmonising causes, and if an exhibitor prefers to use his own show cases no objection will be made provided such show cases are sympathetic to the general scheme of decoration and surroundings. Designs of show cases and the proposed decorations will be on view at the offices of the Exhibitions' Branch of the Board of Trade at an early date.

In view of the great efforts which it is stated will be made by France, Germany, Italy, the United States, and certainly by Belgium itself, to give a most effective display of the most up-to-date machinery, the Royal Commission are desirous of assisting in every way to make the British machinery exhibit unrivalled. With that view the Commission will defray 50 per cent. of the charges made by the Belgian Administration for the supply of steam, gas and electricity, when used for showing machinery producing finished articles, or illustrating a process of manufacture. This should be a most welcome reduction of expense, judging by the complaints of costs made by machinery exhibitors at previous World's Fairs.

Another great convenience and saving of time and expense to machinery exhibitors has also been most thoughtfully considered by the Royal Commission. Exhibitors requiring foundations or shafting for machinery must provide them at their own cost, but can, upon sending to the offices of the Royal Commission drawings with metric measurements, have estimates obtained for them from Belgian contractors, and the work carried out under the superintendence of a competent engineer employed by the Royal Commission. No charge will be made to exhibitors for assistance rendered in this connection. Hitherto machinery exhibitors have had to send their own constructors and engineers to superintend, frequently resulting in weeks of idle delay and unremunerative expense for expert artisans forced to await their turn. Estimates from a reliable contractor in Brussels, under the supervision of the Royal Commission, will be supplied on written request to the General Commissioner at Queen Anne's Chambers, and other estimates from equally reliable sources in Belgium can also be obtained. Crane power will be provided up to seven tons weight free of charge, and special facilities for handling heavier weights can also be secured if application be made.



A special catalogue of the British section will be made in English and French without charge to the exhibitor either for translation or insertion, and all necessary steps will be taken by the Belgian Government for the protection in Belgium of inventions, industrial designs and trade marks shown at the Exhibition.

In regard to the question of dual language, the Royal Commission specially wishes to impress upon exhibitors the desirability of having their trade catalogues and price lists translated into French. Metric equivalents of the dimensions and weights of exhibits may often be given with advantage where such information is required, and the exhibitor's agent should be in a position to quote the purchase price in Belgian currency, inclusive of freight, Custom duties, and other charges. The Customs tariffs of the principal European countries will be filed in the exhibitors' reading room, together with the British commercial directories, a collection of technical dictionaries and telegraph codes.

The report of the committee on previous international exhibitions deplores the fact that in several cases the attendants in charge of stalls at an Exhibition were unable to describe the goods exhibited in a correct or intelligible manner; in other cases their technical knowledge was often thrown away owing to their inability to speak any language but their own.

This statement clearly shows the importance of an active and capable attendant being able to speak French, and other languages perhaps, fluently and technically. The Royal Commission, however, will assist matters to a great extent by providing a special apartment in which exhibitors or their

Digitized by Google

agents may conduct business and deal with their correspondence. A staff of interpreters, acquainted with French, German and Italian, will also be available to afford any assistance and information that may be required.

In future articles the scope of the Exhibition will be described, the progress made in the buildings, the arrangements in regard to tariff, &c., the advantages of international exhibitions in the opinion of the Royal Commission, the chief exhibits expected, the proposed fêtes and sports, and other interesting matter given which will be regularly communicated by the General Commission.

ST. NATHANAEL'S PAROCHIAL HALL, FAZAKERLEY.

THIS building, of which the foundation-stone was laid on May 22, comprises a large hall 62 feet 6 inches long by 36 feet, providing accommodation for 500, and a small hall at the north end 34 feet long by 22 feet wide. The principal entrance is from Fazakerley Road, where two porches are arranged, the space between forming a recess for the font. As the hall will be used as a mission church until the permanent church is erected, the small hall will be divided into two rooms to form a chancel and vestry. Provision is made for future extension on the east side in the form of a kitchen and ladies' lavatory, together with stairs leading to a class-room to be arranged over present chancel if desired. The building is being built of brick with grey Ravenhead facing to the exterior to height of sill level, the upper portion of the walls being finished with half-timber work. The roof is of red tiles, and has an ornamental bell turret at south end, covered with split oak shingles. The heating is to be effected by means of gas radiators, and the ventilation by inlets in the walls and extractor on the ridge. The work is being executed from the designs of Mr. FRANK RIMMINGTON, architect, Harrington Chambers, 26 North John Street, Liverpool, at a cost of 1,400*l*. The contractors for the work are Messrs. WOODS, BENSON & Co., of Stanley Road, Liverpool.

LEWES VICTORIA HOSPITAL.

THE foundation-stone of the new building for this hospital was laid on June 9 by H.R.H. the Duchess of Albany in the presence of a distinguished company, including the Duke and Duchess of Norfolk, Viscount and Viscountess Gage, the Archdeacon of Lewes, and many of the notables of the county and the town of Lewes. The building is designed by Messrs. Ernest Rüntz & Ford, and will be in red brick, with quoins, &c., of a darker red than the main building. The porch will be in stone, having the coats of arms of the county and the town on either side of the carved lunette window over doorway. The eaves and gables will be finished with stone cornices, and the roof covered with sand-faced tiles, the treatment being appropriately in the Georgian style, as there are many fine old buildings of this type in the town and neighbourhood, which by their simplicity of design and accuracy of proportion are pleasing and restful, and retain that quiet refined dignity peculiar to our cathedral and county towns.

The building is being erected on the Downs at the back of the County Prison and facing Neville Road; it is on high ground, having an extensive view of the town.

There are two principal wards on either side of the main block, one being for males and the other for females. The wards are 32 feet long and 19 feet wide, with ample windows and fireplaces, besides being heated by hot water and well ventilated. Each ward will have at the back, along the whole length of wards, covered verandahs, so that the patients may be wheeled in their beds through French casement windows to enjoy the fresh air and sunlight without suffering the least inconvenience or fatigue; and for the purpose of obtaining all the sunlight possible, the wards have been placed obliquely on plan, but care has been taken to avoid the patients being inconvenienced through being unduly exposed to the glare and heat of the midday sun.

The two wards will be connected by a wide corridor running through the centre of the building, off which will be entered special wards, one adjoining the main ward for females and the other adjoining the main ward for males. At either side of the main entrance are placed the matron's room and waiting-room, and the main entrance corridor intersects the previously mentioned corridor and runs in

Digitized by Google

direct line to the operating and anæsthetic room. The kitchen, &c., are placed on the north side of the building, and the nurses' sitting-room on the south side.

The patients' entrance is placed on the south side of the building, from which wide corridors connect the hospital and dispensary and out-patients' rooms, which are placed at the back of the building. There will be a small laundry adjoining the north side of the latter.

The anæsthetic room adjoins the operating-room, and patients to be operated upon will be first treated in the former and then wheeled through the connecting doorway to the adjoining room. The floor of these rooms will be of marble terazzo, and the walls and ceilings covered with patent tiling, and the room well lighted and ventilated.

From the centre of the main block there will be an oak staircase leading to the first floor, where provision is made for bedrooms and bathroom for the staff, and in the attic floor will be placed the servants' bedrooms, storeroom, &c.

As well as the wards, the principal corridors, anæsthetic and operating-room and out-patients' room will be heated with hot water, and it is proposed to light the building by electricity.

The floors to wards, corridors and lavatories and bathroom will be laid with a patent material warm to the feet and jointless to prevent dust accumulating, and to assist in this all angles at junctions of floors, ceilings, &c., will be rounded off throughout the building.

The walls to lavatory and bathroom will be lined with patent tile, and the sanitary fittings throughout will comprise the latest ideas in sanitary science.

There will be a small detached mortuary, and from a careful study of the plans provision appears to be made for all the necessary stores, cupboards, &c.

THE INSTITUTION OF GAS ENGINEERS.*

THE belief has recently become prevalent that the illuminating efficiency of a combustible gas used in conjunction with an incandescent mantle is proportional to its net calorific value. The basis of this belief seems to be the investigations carried out by Messrs. White, Russell and Travers in the United States in 1901-2, and more recently by M. Sainte-Claire Deville, of Paris, in 1907. The experiments of Messrs. White, Russell and Travers, which were embodied in a paper read before the Michigan Gas Association in 1902, consisted in a comparison between the net calorific values of various gases and their illuminating efficiencies in conjunction with the incandescent mantle when burnt in an ordinary atmospheric burner properly adjusted so as to give the maximum effect. They concluded:—

1. That no matter what gas was being used with the mantle—whether water gas, coal gas or natural gas—that the point of highest efficiency corresponded also with the point of maximum illumination.

2. That the illuminating efficiency was proportional to the calorific value of the gas approximately in the proportion of one-candle-power cubic foot for every four calories increase in the net heating value.

White, Russell and Travers's Table.

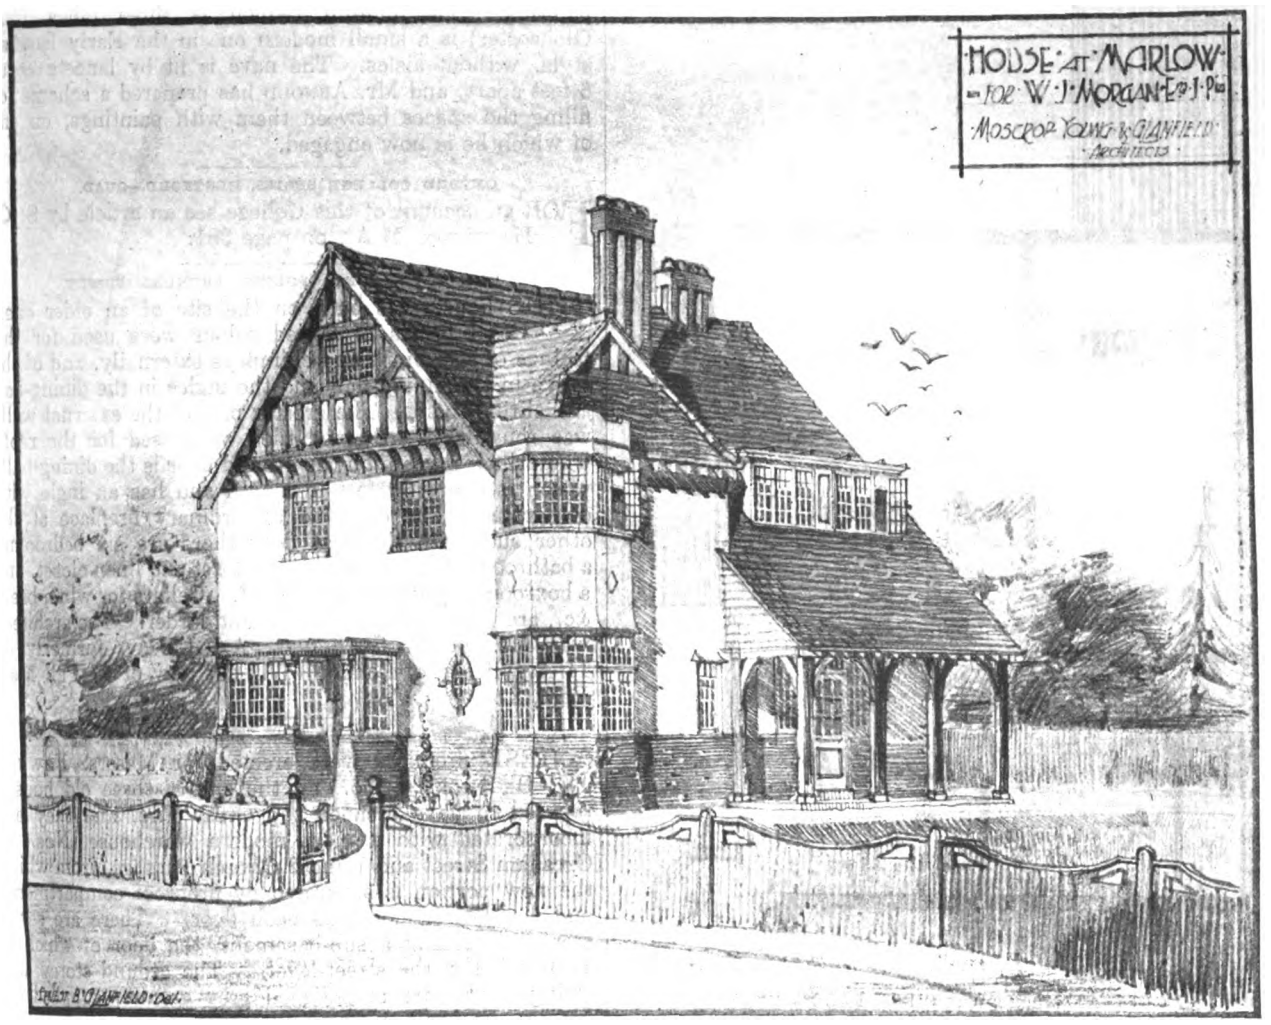
Gas.	Net Calorific Value.	Candles per Cubic Foot.	Calories per Candle.
Water	60·24	5·53	10·89
Water and coal	108·9	17·5	6·22
Decarburised coal	130·9	21·86	5·99
Coal	144·3	25·4	5·68
Coal and carburetted water	147·86	28·48	5·19
Coal gas and benzolated coal	153·83	27·4	5·61
Benzolated coal	156·1	29·75	5·25
Carburetted water	169·6	32·9	5·15
Carbon monoxide	67·03	5·54	12·10
Carbon monoxide and coal	112·11	20·69	5·42
Hydrogen	62·39	9·67	6·45
Pintsch	239·38	41·63	5·75
Natural	219·28	22·94	9·56
Coal and natural	162·96	25·43	6·41
Coal	140·55	25·60	5·49

* Abstract from a paper on "A Comparison Between the Illuminating Efficiencies of Carbon Monoxide and Hydrogen when used in Conjunction with the Incandescent Mantle." By Arthur Forshaw, M.Sc., Institution Research Fellow in the Department of Fuel and Gas Engineering, the University of Leeds.

An examination of the table of results published with their paper—the essential parts of which, together with an additional column showing the number of calories per candle per hour, which should be a constant, are reproduced below—shows that whereas out of fifteen different gases ten behaved in a manner consistent with the second of their conclusions and two others approximately so, three gases—viz. water gas, carbon monoxide and natural gas—were notable exceptions.

M. Sainte-Clair Deville investigated a number of different composite gases, comprising "blue" water gas, coal gas and various mixtures of the two, whose net calorific values varied between 76.8 and 208.8 calories per cubic foot (water gas to cannel gas). He employed an atmospheric burner specially constructed so that the relative proportions of air and gas in the mixture could be accurately measured. He found that the duty of a given gas (defined as candles per cubic foot per hour when the proportion of air admitted with the gas is so adjusted as to give the highest illuminating effect for the particular rate of gas consumption) invariably increased with the rate of consumption up to a certain maximum. Beyond this maximum an increase in the rate of consumption caused no further increase in the duty, which, after remaining constant within a certain limited range of consumption, depending upon the size of the mantle, at length fell off considerably. Taking in each case this maximum duty as the proper basis of comparison with the different gaseous mixtures examined, he concluded that:—

1. The duty obtained for the expenditure of a given number of units of heat per hour remains constant within 15 per cent. throughout the whole range of illuminating gas from neat water gas to neat cannel gas.



2. That, therefore, it must be granted that the specific or normal illuminating duty in the incandescent burner is proportional to the calorific value of the gas.

Without questioning the accuracy of M. Sainte-Claire Deville's observations, it seems difficult to attach any physical meaning to the supposed simple connection between the calorific value of a gas and its illuminating efficiency, whatever view is taken of the cause of luminosity of the mantle. For if it be supposed that the mantle is a "light heat-engine," which in some way emits intense luminous radiations as the result of its being heated in the flame to a high temperature, the proposition that the luminous effect is proportional to the calorific value of the gas (which probably would bear some simple relation to the flame temperature) hardly seems consistent with what is known concerning the relationship between the total amount of radiation emitted by an incandescent solid and its temperature. Or, on the other hand, if it be argued that the luminosity of the mantle is connected with a supposed power of inducing surface combustion—a cause which may at least in part be operative—it must be admitted that its action in this respect will probably be selective with regard to the constituents of a given combustible mixture, and that any such selective action will depend chiefly on chemical factors, and will have no necessary or even obvious connection with the total calorific value of the gas.

It may be observed that, with few exceptions, the comparisons so far made between the illuminating values of various gases and their calorific powers have had reference to more or less complex mixtures of gases, and that the results of such experiments as have been made with single gases, or with mixtures of two gases, are precisely those which do not conform to the conclusions drawn from the more complex cases. This is particularly so with regard to the results obtained by the American investigators. When, therefore, it was suggested to the author, at the time of his appointment to the Gas Fellowship at the University of Leeds, that he should, as part of his work, investigate the question de novo from a fundamental standpoint, it seemed desirable that a careful series of comparative experiments should be first of all made with one or two gases in a state of purity, and for this purpose hydrogen and carbon monoxide seemed to possess qualities which eminently fitted them for such a comparison.

In the first place these two gases are similar in having nearly the same net calorific values—namely, carbon monoxide = 85.9 kg. cent. units, and hydrogen = 72.8 kg. cent. units per cubic foot at 0° C. and 760 mm.—and also in requiring exactly the same proportion of oxygen (or air) for their complete combustion. But here their similarity ends. They differ in two important respects—namely, in density and in what may be termed, for want of a better phrase, their "combustion intensities." The density of carbon monoxide is fourteen times that of hydrogen (and therefore their

Digitized by Google

relative diffusibilities are as 1 is to 3.74); and not only is the rate of combustion of hydrogen known to be very much higher than that of carbon monoxide, but also their rates are unequally accelerated by the influence of hot surfaces.

It was therefore decided to make a systematic investigation of the mantle efficiencies of these two gases and the conditions requisite for the attainment of the maximum illumination from each, with a view to determining whether, with two single gases having nearly the same calorific values, but exhibiting considerable differences in the character of their flames and their modes of combustion, the supposed dependence of illuminating effect upon the calorific values could be verified.

The principal conclusions arrived at during this investigation may be summarised as follows:—

1. When hydrogen is burnt in an ordinary atmospheric burner with a degree of aeration up to a ratio of $\frac{Air}{H_2}=0{\cdot}5$—i.e. the highest possible with such a burner—the duty afforded steadily decreases with a rising rate of gas consumption.

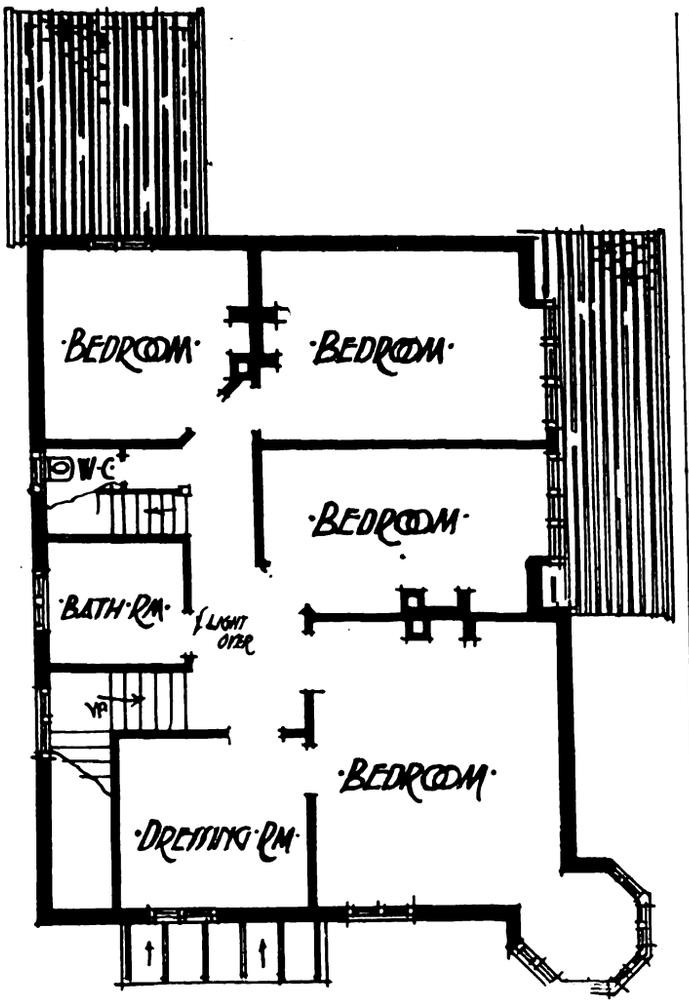
2. The distribution of luminosity over the mantle with such a burner is vastly different with hydrogen than with carbon monoxide under similar conditions.

3. With an ordinary burner carbon monoxide invariably gives a very much higher duty than hydrogen.

4. When, by suitable manipulation, hydrogen was made to burn in a well-aërated condition, the highest duty obtained was 11.7 candles per cubic foot, with a ratio of $\frac{Air}{H_2}$ = about 1.7. This, compared with the best results for carbon monoxide—viz. 17.3 candles per cubic foot with a ratio $\frac{Air}{CO}=1.9$—shows a 48 per cent. margin in favour of carbon monoxide. A comparison of their calorific values as used in the test shows only a 13 per cent. advantage in favour of carbon monoxide.

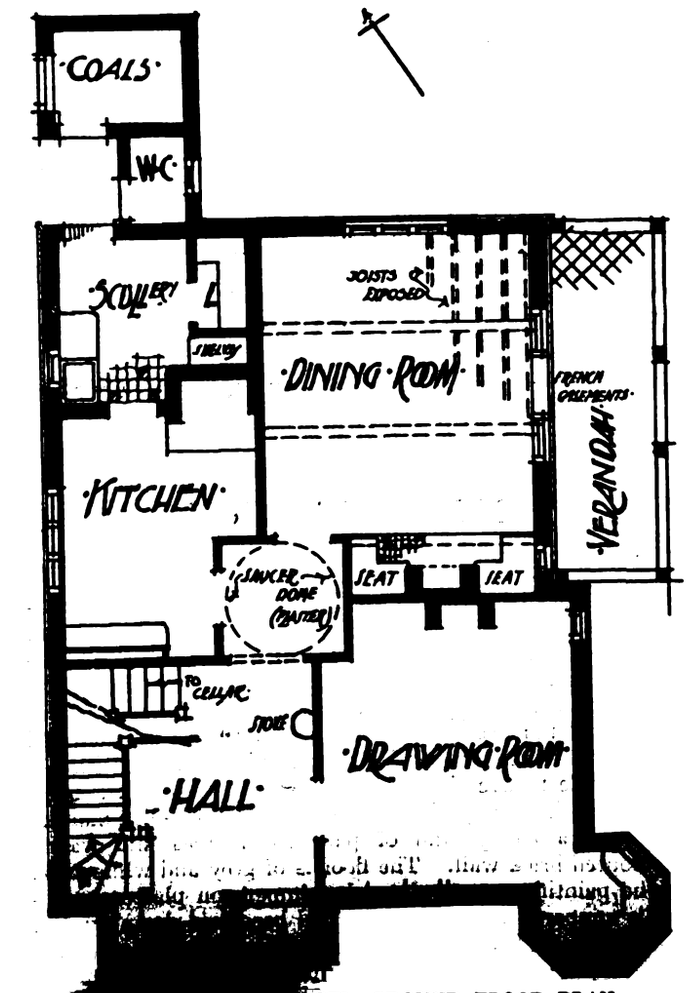
5. The use of cones inside the mantle causes a quickening of combustion and concentration of illumination.

HOUSE AT MARLOW.



THIS house is erected at Great Marlow, Bucks. The accommodation is as follows:—Ground floor, large dining-room, opening out on to a verandah, with inglenook, drawing-room, sitting hall, kitchen, and the usual offices. First floor, five bedrooms, bath-room, and w.c., and in the roof large bedroom, servants' bath-room, box-room, and hot linen cupboard. Half-timber work of gables is treated with "Matsine," the roof tiled with sand-faced red and purple tiles, and the chimneys are red and purple brickwork, with rough-cast panels. The octagon in the drawing was designed in deference to the wishes of the client, as there is a good view of Quarry Woods therefrom. The contractors were Messrs. W. & T. SELLMAN, of Great Marlow, and the architects Messrs. MOSCROP-YOUNG & GLANFIELD, of 12 Buckingham Street, Strand, W.C.

ILLUSTRATIONS.



"THE ANNUNCIATION."—CARTOON FOR TEMPERA PAINTING IN MATSON CHURCH, GLOUCESTER.

THIS wall painting is by Mr. HUGH ARNOLD, stained-glass worker, Kensington, W. It is 6 feet wide, and occupies a space under the west window of the church on a level with the eye. The colour scheme has been kept rather quiet and delicate, with the colours in broad flat masses. The angel is in a rose-coloured dalmatic—the brightest bit of colour in the composition—with pale mauve-blue mantle; and the VIRGIN in creamy white with warm pink shadows and dark grey-blue mantle, against a background of pale green trees and warm-coloured brick wall. The floor is of grey and white tiles. The painting was executed in tempera on plaster, specially prepared from lime that had been laid down by Mr. J. D. BATTEN some years ago. The method of painting is simple, the colours being ground in water and mixed with a medium of yolk of egg and water in the act of

GROUND FLOOR PLAN.

painting. The church (which is three miles from Gloucester) is a small modern one in the Early English style, without aisles. The nave is lit by lancets about 6 feet apart, and Mr. ARNOLD has prepared a scheme for filling the spaces between them with paintings, on one of which he is now engaged.

OXFORD COLLEGE SERIES, HERTFORD.—QUAD.

FOR an account of this College see an article by S. G. HAMILTON, M.A., on page 381.

THE DOVER, NEAR POLING, ARUNDEL, SUSSEX.

THIS house was built on the site of an older one. Local bricks of varied colour were used for the facings of the plinth and chimneys externally, and of the frieze in the dining-hall and the ingles in the dining-hall and sitting-room. The greater part of the external walls was rough-cast. Stained tiles were used for the roof. The principal room on the ground floor is the dining-hall, which is about 30 feet in length and has an ingle with dog-grate at one end and an ordinary fireplace at the other end. On the first floor there are six bedrooms, a bathroom, w.c., housemaid's closet and linen closet, and a boxroom is provided in the roof. Cellars for wine, beer, &c., are built under the pantry and larder. The architect was Mr. G. L. SUTCLIFFE, A.R.I.B.A., formerly of 11 Argyll Place, London, W., but now of 17 Pall Mall East, London, S.W.

NEW BUSINESS PREMISES, ALDERMANBURY, E.C.

THESE premises were erected for Messrs. FOWNES BROTHERS & Co., on the site of three old houses reputed to have escaped the Great Fire, and they are incorporated with a more modern warehouse, Nos. 75 Gresham Street and 1 and 2 Church Passage, from which the new portion is separated by fireproof compartments and double iron doors on each floor. There are seven storeys including a sub-basement, the floor of which is 18 feet below the street-level. The ground storey and string course are of polished grey granite, supplied by Messrs. FENNING & Co., and the elevations above are in Farnley salt glazed bricks and Portland stone. The window-frames are of oak and the casements of gunmetal, by Messrs. WILLIAM MORRIS & Co., glazed with polished plate. The constructional steelwork was supplied by Messrs. RICHARD MORELAND & SON, and the floors by the Kleine Floor Syndicate, all exposed girders and columns being encased in cement. The floor-boarding is 1¼-inch rebated, grooved and tongued oak in 4½-inch widths, and the flats are laid with Seyssel asphalte.

The pavement and stall-board lights and the iron doors The pavement and stall-board lights and the iron doors were supplied by Messrs. HAYWARD BROTHERS & ECKSTEIN, and the revolving entrance door by the Van Kannel Syndicate. The new and old premises are furnished throughout with a complete installation of electric fire alarms, internal "sprinklers," and external "drenchers." The whole of the brickwork was built in cement, and Sirapite plaster was used throughout. The stone carving was executed by Mr. GILBERT SEALE. A spiral iron parcel-transporter, supplied by Messrs. SAUVEE & Co., runs from the top floor to the basement. Messrs. F. & H. F. HIGGS, of Herne Hill, were the builders, and they also supplied the whole of the interior fittings, which were specially designed by the architect, Mr. HARVEY DYBALL. Mr. J. ARMSTRONG acted as clerk of works. Several interesting relics were unearthed in excavating the sub-basement, including some oak camp-sheeting along the bank of an old watercourse about 22 feet below street level, and a shallow well steined with rough ragstone on a massive oak cill, the timber in both cases being perfectly sound.

HOUSE AT EDGBASTON, BIRMINGHAM.

THE walls are faced with thin black country bricks with wide joints, and the roofs covered with hand-made tiles. All external woodwork painted white. The contract amounted to about 3,700*l*., and was carried out by Messrs. J. BARNSLEY & SONS, from the designs of Messrs. COSSINS, PEACOCK & BEWLAY, Birmingham.

CASHEL.

ROCK OF CASHEL, TIPPERARY.

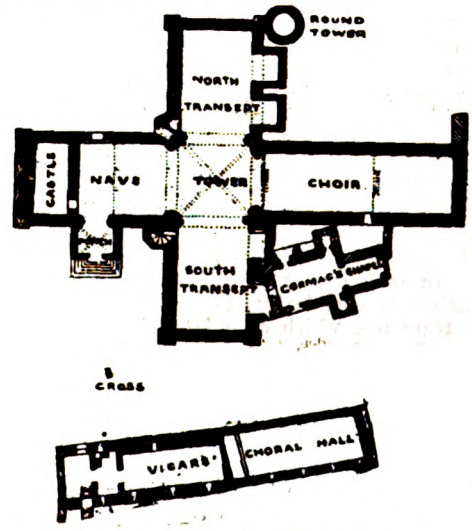
ON October 27, 1874, the Church Temporalities Commission, under the provisions of section 25 of the Irish Church Act, vested "the ruins of the ancient cathedral church on the 'Rock of Cashel' with the land adjacent thereto" in the Commissioners of Public Works, to be preserved as a national monument, and possession was given to the Board by the Dean and Chapter.

This vesting of the property in the Board, however, did not give them any control over the burials either inside the ruin or in the graveyard outside. The solid rock comes near the surface, and generally there is only about 2 feet in depth of earth. To make up for this deficiency, a large mound of earth is raised over each grave, as the coffins would come within a few inches of the surface. On representations made to the Local Government Board, after an inquiry held, interments inside the walls of the cathedral were prohibited except in the case of two families, but the interments outside continue as before, and seldom comply with the Burials Regulation Act as regards depth below the surface of the ground. In the adjoining ruins of St. Dominick's Abbey (a Dominican monastery of the thirteenth century) and at Hore Abbey (a twelfth-century Cistercian House), the interior is so taken up with graves and kept in such a neglected state that proper repairs can only be effected with difficulty. At Holycross Abbey, a few miles from Cashel, the whole of the nave, choir and transepts have been turned into a badly-kept graveyard, over the burials in which the Board have no control.

The Commissioners of Public Works in their last annual report give a detailed account of the building. The ruins at Cashel are in the townland of "St. Patrick's Rock" and the parish of the same name. The place was occupied about the beginning of the fifth century by the King of Munster, who fortified it, and thenceforward it took the name of Caiseal or Cashel from the stone fort then erected there.

The Round Tower.

The oldest building on this site is the round tower, now incorporated with the cathedral, and forming a picturesque addition at the N.E. angle of the north transept where there is a doorway into it from the triforium of the cathedral.



The round tower is formed of masonry varying in character, but generally composed of large stones, some of them of somewhat cyclopean character, and formed with articulated joints. It is probably of the tenth century; the height is about 85 feet, the walls are 4 feet in thickness at ground level, and the actual circumference is 51 feet. There is the usual round-headed doorway, which is 11 feet 8 inches above the ground, and 5 feet 6 inches high. The tower has four angle-headed openings at the top, the heads of two of which are peculiar as being cut each out of one solid stone.

There is now no trace of the early church to which the round tower formed an adjunct. The earliest ecclesiastical record here relates to Cormac, son of Cuilennain, a prince who was also a bishop, born A.D. 831, and slain 903.

Cormac's Chapel.

Next to the tower in chronological order is the beautiful little Romanesque church known as Cormac's chapel. The first historical record relating to it shows that it was founded in 1127 by Cormac M'Carthy, King of Desmond, who was also Bishop of Cashel. The dimensions of this church, which is the most perfect example of Romanesque work in Ireland, are as follows:—The nave spanned by a barrel vault is 29 feet 8 inches by 17 feet 8 inches. The groined chancel is 13 feet 8 inches by 10 feet 10 inches. The croft over nave 27 feet 2 inches by 16 feet 2 inches, and the croft over chancel 12 feet 6 inches by 11 feet 5 inches.

The nave and chancel are covered by steep-pitched stone roofs constructed on the corbel principle, each having a chamber between the external stone roof and the internal stone vault. The plans show both floors, and the elevations give a representation of the two square towers at the junction of the nave and chancel occupying the position in which the transepts of later churches are to be found and giving a cruciform character to the plan.

The south tower has an embattled coping, but this is a later addition. Formerly it had a conical cap like the north tower. The surfaces of the walls of the church are richly ornamented internally, as well as externally, the chief feature being the elaborate arcading, in the panels of which diaper work was painted, and the walls and ceiling of the chancel were ornamented with figure subjects. The two

Digitized by Google

square-headed window openings in the south elevation are insertions of comparatively late date. The orientation of the building is peculiar, being sixteen degrees out of the due east and west line, and is different from the orientation of the cathedral; the axis of the chapel does not correspond with the centre line of the nave. The principal doorway is in the north side. It is round-headed and consists of five orders. Over the arch is a high pediment or gable termination. In the tympanum over the doorway is the carved figure of a centaur shooting with bow and arrow at a lion. There is a plainer doorway in the south wall of nave. There is a wonderful variety of sculptures in the capitals of the shafts, and double columns with grotesque heads, ornaments and terminating mouldings. Dr. Petrie gives illustrations of upwards of forty of these in his "Essay on the Ecclesiastical Architecture of Ireland," published in 1845.

The crofts were approached by the staircase in the south tower; there are traces of an upper croft which had timber flooring; the access to it was by means of ladders. The towers act as abutments against the thrust of the vaulting and the heavy stone roofs. The artistic beauty of this gem of Romanesque work is equalled by the boldness of its construction and the skilfulness of its execution. A monograph on this structure containing drawings and photographs, was published by Mr. Arthur Hill, F.R.I.B.A., in 1874, but it has been long out of print.

The Cathedral.

The next historical reference to these buildings is of the date of 1169, when Donald O'Brien, King of Limerick, is said to have founded a new church in which in 1172 Henry II. received the homage of the founder. This church occupied the site of the present cathedral; the latter building is of a date about a century later than Donald O'Brien's church. Its earliest portions belong to the end of the thirteenth century. The principal dimensions are:—Choir, 87 feet 9 inches by 27 feet 6 inches; nave, 36 feet 11 inches by 31 feet 6 inches; space under tower between nave and choir, 42 feet 1 inch by 42 feet 1 inch. Total internal length, 166 feet 9 inches.

The north transept measures 45 feet 4 inches by 31 feet 5 inches, and has two side chapels each 12 feet 10 inches by 11 feet 9 inches. The south transept is 45 feet 3 inches by 31 feet 5 inches, and has two side chapels also, one measuring 13 feet 3 inches by 8 feet 2 inches, and the other 11 feet 8½ inches by 8 feet 3½ inches. The total internal width north to south is 132 feet 8 inches.

The present cathedral occupies the whole of the space between the round tower and Cormac's chapel; the latter was connected with the east side of the south transept, thus forming a suitable chapter room, to which access was obtained by means of a doorway opened in the west gable of the chapel from the south transept, and by another doorway into the chapel through the north tower. The most remarkable feature of this cathedral is the very short nave compared with the length of the choir. The shortness of the nave has given rise to the surmise that the space occupied by the castellated residential structure at the west end of the church may have been taken off the length of the nave. There were no aisles in any portion of the cathedral. The canopied buttresses at the salient angles are interesting, and a peculiarity in construction rarely seen elsewhere is in the re-entrant angle towers at the junctions of nave and transept. Over the piers of the windows in the north and south walls of the choir are a range of small upper clerestory windows with quatrefoil openings externally, while internally they have segmental arches on jambs formed by small pillars, an arrangement not often seen elsewhere.

Another striking feature is the tall and stately windows of the transepts, which at a later date were shortened in height. The triforium is also remarkable. This passage is the thickness of the wall, as shown on the triforium plan, connects the castle at the west end with the two re-entrant towers at the junctions of nave and transept walls, and also with the central tower which crowns the intersection of the transept with the main building.

There seem to have been extensive alterations made in the structure about the end of the fourteenth century, when the central tower was raised, and the roofs were surmounted by embattled parapets. It was probably at this time that the castellated residence at west end of nave was erected—though some of its detail would appear to be somewhat earlier—and the whole appearance then was that of a strongly fortified structure calculated to stand a siege; at this time the enclosure was surrounded by a loopholed wall. The castle was adapted for the residence of the Archbishop, and in addition to the space it occupies 31 feet 7 inches by 14 feet 10 inches internally, the space over the southern porch for two storeys in height was used for residential purposes, and was approached directly from the castle.

There was a gallery, or floor, over the nave, and into this there was an opening from the castle. This space over the nave may have been used as an extension for residential purposes. There are pier and angle shafts sufficient to carry a wooden floor, but hardly indicative of having carried stone vaulting. The cathedral was burned in 1495 by Gerald, Earl of Kildare, who had a grudge against the Archbishop, and defended the act of burning when called to account for it before the King by saying that he thought the Archbishop was inside. The Rock of Cashel was taken by Cromwellian soldiers under Lord Inchiquin in 1647. The church was left in a ruinous condition for a time, was repaired in 1686, and restored as a cathedral in 1729. In 1749 it was unroofed, a new building having been erected.

The vicars choral buildings were erected apparently in the fifteenth century with alterations in the seventeenth. They occupy the southern portion of the enclosure; the architecture is of a domestic character. Houses of residence for vicars—who were those members of a cathedral corporation who did not belong to the chapter—were anciently attached to many cathedral churches. Vicars choral as a rule were laymen appointed to assist in chanting the service, and were sometimes minor canons attached to the cathedral. Originally the vicars were eight in number. They were endowed with lands and had a seal as a corporate body. The number was afterwards reduced to five, and a change was made appointing clergymen as honorary vicars, who appointed singing men at a salary as their deputies. This continued until 1836, when they were abolished and their rights and property vested in the Ecclesiastical Commissioners. The residential accommodation provided was on a liberal scale.

THE PRESERVATION OF IRON AND STEEL.*

(*Concluded from page* 388.)

THE preservation of iron is, of course, a problem which, in the ease of its solution, varies directly with the rust-resisting character of the metal to be preserved. For this reason a number of the progressive steel manufacturers in the United States, and presumably elsewhere, have been for some time past investigating methods of manufacturing rust-resistant steel. It is not the author's intention at this time to go deeply into this phase of the problem, but it seems to be a fact that carefully made, open-hearth metal, in which the ordinary impurities are cut down to mere traces, and in which the heat treatment has been carefully controlled, is much more resistant to corrosion than the ordinary types of metal with a comparatively high percentage of impurities. The author is well aware that reducing the content of impurities can only be achieved at the expense of tensile strength and perhaps other characteristics of steel as well, but for certain purposes great strength can be sacrificed to longevity.

There is now being manufactured in several rolling-mills in the United States an extremely pure metal which contains, according to analysis, about 99.95 per cent. iron. The only impurities which this metal contains are sulphur (0.019), phosphorus (0.004), and carbon (0.026). This pure iron is manufactured in basic, open-hearth, 50-ton converters, and is smelted from pure pig iron and carefully selected high-grade scrap. There is no mystery about its manufacture, everything depending from start to finish on the heat treatment which the metal receives.

In the opinion of the author resistance to corrosion is attained largely by a study of the proper heat treatment of the metal and of the amount of working which it has received, both in the hot and cold rolls. Up to the present time this pure iron manufactured by a steel process has been used for the preparation of sheet and plate only. It has been demonstrated, however, that wire can be made from it. The demand for this type of metal appears to be growing, and it has been largely used for the manufacture of road culverts. In the letter of transmittal accompanying the author's bulletin on "The Corrosion of Iron," it was stated that the development of a sheet-iron culvert, which shall be at the same time strong, light, and resistant to corrosion,

* A paper by Allerton S. Cushman, Assistant Director, Office of Public Roads, United States Department of Agriculture, presented to the Iron and Steel Institute.

Digitized by Google

would be of great assistance to road builders. The fact that this new metal has been largely specified by culvert manufacturers, even at a somewhat added cost, is the best evidence that it is meeting a long felt want in this and allied industries. There would seem to be no reason why such a pure iron, if it receives the proper heat treatment and rolling, should not be found as resistant to corrosion as the pure iron made by the older processes.

Many metallurgists believe that the resistance to corrosion exhibited by some wrought irons is due to the slag and cinder inclusions which are always found in this type of metal. Microscopic examination does not, however, justify this conclusion, as the slag and cinder are found to lie in definite streaks or cleavage lines in the rolled iron. There is no evidence to show that the fibres of wrought iron are enclosed by cinder, as has been claimed by certain metallurgists. Impure wrought irons, which have been prepared by what is known as the "busheling process," also contain the full amount of cinder inclusion, and yet are not at all resistant to corrosion. While it is undoubtedly true that the tendency of iron to rust is an elementary characteristic of the metal itself, there is, nevertheless, abundant evidence to show that very pure iron does not exhibit a tendency to dangerous pitting, or localised corrosion, to the same extent as more impure and carelessly manufactured steel. Passing over the metallurgical and economic problems involved in the manufacture of rust-resistant steel, we will proceed to the discussion of the methods of preservation which depend upon covering iron with other metals.

Preservation with Zinc.

As is well known, zinc is applied to the surface of iron by several different processes which may be classified as the hot-dip method, which is misnamed galvanising; the cold electro-plating method; and the vapour or dry-heat process known as Sherardising. Zinc is electro-positive to iron, and when the two metals are in contact and wet with a corroding solution zinc will pass into solution and the iron will be protected. The sphere of influence of the zinc does not, however, extend far from the point of contact between the two metals, so that iron can begin to rust in places long before all the zinc is destroyed. This can easily be shown by soldering a button of zinc into the machined surface of a plate of steel and immersing the whole either in water or in the ferroxyl indicator. It is, of course, true that the more corrosive the action the larger will be the sphere of influence of the protecting zinc, and the faster the destruction of the zinc will proceed.

The function of the zinc coating in the ordinary galvanising process is a double one; first, to cover the iron so that water and oxygen cannot come in contact with it; and second, to protect the iron at its own expense if pinholes or cracks in the zinc surface exist. Generally speaking, the more zinc that can be put on, the more efficient the protection; but there are decided practical limits to the amount of zinc that can be carried by an iron surface. If the material must undergo bending in use, the heavier the coating the greater the danger of cracking. Thus wire which is to be used in single strands, as, for instance, in telegraphy, can be "double galvanised," and unwiped, whereas wire which is to be woven into fences must carry a thinner coating and be wiped smooth. So-called "double galvanised" wire is not dipped twice into the bath of molten zinc, but merely carries about twice as much zinc by weight as ordinary wire. In the hot-dip galvanising process it is customary in American practice to wet the iron with a soldering solution just before its immersion in the zinc bath. This soldering solution is generally an acid bath containing zinc chloride. The electro-chemical explanation of corrosion indicates that this is a dangerous practice for which metallurgists should find a substitute. That some of the electrolytes are included under the zinc coating can hardly be doubted. The system Fe—$FeCl_2$—$ZnCl_2$—Zn is a galvanic couple which, however well it may justify the name of "galvanised iron," would certainly tend to hasten corrosion.

The electro-chemical theory suggests the possibility of devising an inhibitive soldering solution as a substitute for the acid treatment. The author, in co-operation with Mr. A. H. Gardner, has found that zinc oxide dissolved in an alkaline bath gives promise of a successful solution of this problem. The cold galvanising or electro-plating method of coating iron with zinc is open to the same criticism as the hot-dip method, inasmuch as the deposition is made from an acid bath, with the inevitable inclusion of some of the electrolyte. The vapour deposition processes, such as that of Cowper-Coles, avoid this difficulty; but it is by no means certain that they do not introduce other dangerous factors. Although zinc is electro-positive to iron certain alloys of zinc and iron are electro-negative. If these alloys are formed in the Sherardising process, we defeat our main purpose in using zinc as a protective agent. At all events the superior protective effect of zinc deposited by a vapour-coating process may be said, as far as the United States is concerned, to be still on trial. In the Sherardising process the material to be coated is packed into air-tight iron drums together with zinc flue dust from the smelters. These drums are then heated for a certain length of time at a temperature below the melting-point of zinc. The drums are also in some cases made to revolve while the heating is going on. By this means a very efficient coating of zinc is applied to the surface of the metal. For certain purposes this process may prove to be of value.

At the request of the author, a number of interesting tests have recently been undertaken for the purpose of ascertaining the relative resistance to corrosion of steel wires of varying chemical compositions, and also to show the relative value of protective coatings.

With these ends in view, twelve samples of galvanised steel wire were manufactured by a prominent steel and wire manufacturing company. They have been put up in the form of fence and exposed to the action of the weather. These twelve samples fall into three groups, which will be described in the order in which they were made.

The first sample was a wire of the following composition:—

	Per cent.
Carbon	0.66
Manganese	0.84
Sulphur	0.028
Phosphorus	0.016

This was made in a prominent Western steel mill by the basic open-hearth method. The ingots were cast July 23, 1908, and were reheated and rolled into billets the same day. On the following day they were again heated to redness and rolled into $\frac{5}{8}$-inch rods. One billet was taken at random from the lot for the purpose of this test. The rod after cooling was cleaned by immersion in hot dilute sulphuric acid, then rinsed with water and dipped into milk of lime. After drying, the rod was drawn cold into 9-gauge wire. It was then galvanised by passing it through a furnace in which it was heated to dull redness, and then into a bath of hydrochloric acid containing zinc chloride, and lastly into a bath of molten zinc. This wire was not wiped—that is to say, it was allowed to retain as much zinc as would adhere to it. This sample was designated C 1, and it is purposed to test it against any of the low carbon, low manganese wires to be described later, and which may for this purpose be regarded as C 2.

The second group consists of six samples of "American" style, 8-strand fabricated fencing, 45 inches high. The object of this group is to determine the effect, if any, of segregation of the impurities in the iron. Therefore the six samples were taken from the same heat. The steel was made at the same mill and on the same day as sample C 1, but by the Bessemer process and was cast in six ingots. As these ingots were rolled, two billets were taken from the top of the first ingot, two billets from the middle of the first ingot, and two from the bottom of the first ingot. These three pairs of billets were marked respectively A 1, A 2 and A 3. Similarly, from the last ingot of the heat two billets were taken from the top, two from the middle, and two from the bottom. These three pairs of billets were marked respectively B 1, B 2 and B 3. These were all rolled hot into rods, and, after cooling and cleaning in the manner described above, were drawn into wire. The six samples were each divided into three portions. About half of each sample was drawn into 11-gauge wire, a quarter of each sample into 9-gauge wire, and the remaining quarter into 12-gauge wire. This was because these three sizes of wire are all used in making the standard "American" fence, the 9-gauge for the top and bottom horizontal strands, the 11-gauge for the intermediate strands, and the 12-gauge for the vertical connecting wires. Immediately after being drawn the wire was galvanised in the same manner as described for sample C 1, except that on emerging from the molten zinc it was wiped by a mechanical device which left only a thin, smooth coating of zinc on the steel. A separate piece of fencing about 300 feet in length was then woven from each of the samples. These six pieces of fencing then represented the top, middle and bottom of the first and last ingots of the heat respectively. The samples

Digitized by Google

were not analysed separately, but an analysis of the heat as a whole showed the following composition:—

	Per cent.
Carbon	0.9
Manganese	0.55
Sulphur	0.045
Phosphorus	0.092

The third group consists of five samples of basic open-hearth steel, showing increasing amounts of manganese from 0.07 per cent. to 0.37 per cent. These were all made in one furnace between August 18 and August 22, 1908. The process of manufacture throughout was identical with that employed on the sample designated C 1, except that the wire was wiped during the process of galvanising. These five samples were all drawn to 11-gauge and are designated by their "heat numbers," which are given here, together with the analyses.

Analyses of Five Samples forming the Third Group.

Heat Numbers.	Carbon.	Manganese.	Sulphur.	Phosphorus.
	Per cent.	Per cent.	Per cent.	Per cent.
8118	0·05	0·12	0·014	0·014
8119	0·04	0·07	0·014	0·014
8120	0·05	0·16	0·010	0·010
8121	0·05	0·24	0·018	0·018
8122	0·06	0·37	0·013	0·016

All the wire described above was shipped to Pittsburg, Pa., and between September 23 and September 26, 1908, was put up in the grounds of the Carnegie Technical Schools. The site assigned for this purpose is a level strip of ground at the bottom of a deep and narrow natural depression to the north of the quadrangle of school buildings. Because of this location none of the wire will be exposed to the action of wind, but all will show the effects of fog and dampness, which are very prevalent in this hollow.

In addition to the test fences described above, a number of panels have been mounted on either side of the original rows in order to test different methods of providing protective coatings for ordinary steel-wire fences. The barbed wire was treated in the following way:—Ten 80-rod spools of 4-point galvanised wire were run through the spelter after fabrication and 96 lb. of spelter added to the total weight. They were then given one coat of regular barbed-wire dipping paint. One panel of American style woven-wire fence is galvanised by the cold or electro-plating process; another panel is made of double galvanised wire carrying about the same weight of zinc as is usually specified for telegraph wire. This galvanising has been done by a special adaptation and variation of the ordinary hot-dip process, and has not been subjected to the acid bath before galvanising. A third panel is coated with zinc by the Sherardising process. A number of panels, in part galvanised by the ordinary hot-dip process and in part ungalvanised, have been protected by painting with various protective paint coatings. All of these extra panels have been mounted in exactly the same manner and side by side with the samples already described in the foregoing, and the tests should in the course of time yield results of great value.

Preservation with Tin.

Roofing, cans and tinned utensils of all kinds depend for their preservation on a metal coating, which, though not electro-positive to iron, has such a low solution tension that it is known to be practically incorrodible. The difficulty with the use of this metal is that it seems impossible at the present time to apply it economically to the surface of steel so that pinholes shall not exist in the coating. Walker has shown this by an ingenious modification of the ferroxyl test.* A slightly acid solution of gelatin containing a small amount of potassium ferricyanide is flooded, while hot, upon the surface of the tinplate to be tested. The gelatin becomes hard upon cooling, and in a very short time every pinhole on the tin surface is marked by a spot of Turnbull's blue. After the number and position of the pinholes is known, it becomes possible to study ways and means of eradicating them. Hot rolling and ageing of the plates under pressure are among the solutions that have been suggested in the hope that the pinholes will disappear.

The passage of the Food and Drugs Act of 1906 has had a curious and interesting bearing on the tinplate industry in its application to canned goods. Artificial colouring-matter is debarred by this law, and it was found that the natural colour of preserved food-stuff is reduced and destroyed by the action of the tin. In the effort to meet this difficulty the can manufacturers sought to use less tin, and also to lacquer the tinplate so as to prevent its contact with the fruit and vegetable juices. The formation of pinholes has gone on rapidly, however, so that it is not an unusual occurrence to find tinned preserves discharging their juices in tiny streams through small holes resulting from rapid corrosion. Walker's method of examination should prove of great value to manufacturers who have to deal with a problem of this kind.

Preservation with Copper, Lead and other Metals.

It is possible to make a copper-coated steel wire, but this makes an efficient and rust-resistant wire material only when the coating is thorough and homogeneous. Methods are being developed to extend the use of copper for this purpose, and it is also applied now to sheet and plate metal. If the cost is not a prohibitive factor, there would seem to be no reason why steel protected in this way should not come into more general use. The expedient of dipping iron into copper chloride or sulphate baths to supply a preliminary coating of copper before covering with zinc has also been tried. Lead has to some extent been used for covering iron, and for certain purposes this material is useful. It is doubtful, however, whether the application of lead in this way will find a very wide field. Methods have also been tried of applying an alloy of lead and antimony, but the success of the processes is not at present assured. One company in America has already placed on the market steel-sheet coated with this alloy, the success of which will be watched with interest.

Alloys of tin, zinc, antimony and aluminium are also being experimented with and give some promise of success. In all these coatings, however, the use of acid, corrosive soldering fluxes should be avoided.

Preservation with Paint Coatings, Varnishes, Bitumens, Lacquers and Enamels.

The application of paint coatings of various kinds constitutes the method which is most generally depended upon for the preservation of iron and steel. It is along this line that the electro-chemical theories of corrosion appear to find the most important and interesting application. Two years ago, in a paper presented to the American Society for Testing Materials,* the author suggested that, owing to their inhibitive action against rusting, the slightly soluble chromates should be theoretically the best protectives for the first application to iron and steel surfaces. Subsequent investigations, however, showed very conclusively that if the chrome pigment had been precipitated in an acid medium, or for any other reason contained soluble impurities that tended to stimulate corrosion, the surface of the steel might still fare badly. The following account of some special experiments,† a report of which has previously been published, will probably be found interesting in this connection. Samples of bright steel wire were immersed in 100 cubic centimetres of a very dilute one-thousandth normal solution of potassium bichromate in a series of shallow dishes. The wire test-pieces were suspended in the solution so that they did not come in direct contact with the glass surfaces of the dishes. This precaution should never be omitted in experiments of this kind, as, owing to the absorption of air by glass, rusting is always stimulated at the point of contact between glass and iron. The first dish was left as a blank; the second received one drop, equal to $\frac{1}{20}$ cubic centimetre of a dilute tenth-normal copper sulphate solution. The third dish received two drops of the solution, and so on, each dish getting an increased amount of copper sulphate until twenty-five dishes had been prepared.

Now it is apparent that we have in this system two contending forces at work. Iron has a higher solution tension than copper, and therefore tends to pass into solution, the copper tending to plate out on the iron. Chromate ions, on the other hand, put the surface of iron in a condition in which it cannot pass into solution. In the solution system iron-chromate-copper we have an equilibrium to be decided between two contending forces acting in opposite directions. It was interesting and instructive to note the results of this struggle, which was known to be going on, although the actual conflict could not be watched. In the first dish, in which no copper was present, no corrosion took place; in the second also no action was visible. In the third, however, minute specks of iron rust appeared. These were larger and more frequent in the immediately succeeding dishes, the test-

† *Ibid.*, 1908, vol. viii. p. 605.

Digitized by Google

pieces showing rust tuberculation with the well-known pitting effect. As the middle of the series of dishes was approached both iron rust and precipitated copper began to appear side by side on the surface of the iron, and from thereon in the series more and more copper separated, while less and less rust formed, until in the end dishes copper and iron were changing places evenly over the surface without apparent hindrance. These experiments and others of a similar nature were repeated many times with the same results, and there seems to be no escape from at least the following two conclusions to which they obviously lead:—

1. If the surface of iron is subjected to the action of two contending influences, one tending to stimulate corrosion and the other to inhibit it, the result will be a breaking down of the defensive action of the inhibitor at the weakest points, thus localising the action and leading to pitting effects.

2. While the concentration of an inhibitor may be strong enough to prevent the electrolytic exchange between atom and ion, it must be still stronger to prevent entirely the solution of iron and the subsequent oxidation which leads to the formation of rust spots.

If these principles are applied to the selection of inhibitive pigments, it is apparent that many paints may contain substances well adapted for carrying on just such a struggle on the surface of iron. It seems to be the consensus of opinion among experts that an ideal vehicle for spreading pigments does not exist. Linseed oil, well adapted as it is in some respects, not only undergoes complex changes, but absorbs and carries water. Therefore, even when covered with the best paints, the surface of iron is sooner or later subject to attack by the two factors which produce corrosion —viz. hydrogen ions and oxygen.

These considerations suggested that more study should be given to the action of the various pigments which are in general use for compounding paints to be used on steel. A modified form of a test first proposed by G. W. Thompson * was used in the laboratory investigation. A series of bottles, all of the same size, were arranged with two-hole stoppers, so that a current of air could be drawn rapidly through the whole series. Glass tubes connected one bottle to the next in line on the principle of a train of wash-bottles. About fifty typical samples of pigments were obtained in the open market for the test, and after careful sampling were distributed among five independent chemists for investigation.

From the results of their experiments a tentative classification of the pigments was made under the headings:—(1) Inhibitors; (2) indeterminates; (3) stimulators. No one of the fifty pigments tested was, however, admitted to any class except in the cases in which a majority of the investigators reached the same result. The classification reached by this method is shown in the following table:—

Classification of Pigments.

Inhibitors.	Indeterminates.	Stimulators.
Zinc lead chromate.	White lead (quick process; basic carbonate).	Lampblack.
Zinc oxide.	Sublimed lead (basic sulphate).	Precipitated barium sulphate (blanc fixe).
Zinc chromate.	Sublimed blue lead.	Ochre.
Zinc barium chromate.	Lithopone.	Bright red oxide.
Zinc lead, white.	Orange mineral (American).	Carbon black.
Prussian blue (inhibitive).	Red lead.	Graphite No. 2.
Chrome green (blue tone).	Litharge.	Barium sulphate (barytes).
White lead (Dutch process).	Venetian red.	Graphite No. 1.
Ultramarine, blue.	Prince's metallic brown.	Chinese blue (stimulative Prussian).
Willow charcoal.	Calcium carbonate (whiting).	
	Calcium carbonate (precipitated).	
	Calcium sulphate.	
	China clay.	
	Asbestine.	
	American vermilion.	
	Medium chrome yellow.	

It should be carefully noted at this point that well-known pigments, such, for instance, as red lead and litharge, which fall into the indeterminate class, are not thereby impliedly condemned, nor, indeed, are the results of the work given out as a proof of any contention whatsoever. The results should be considered only as a step in a comprehensive investigation, and as preliminary to further studies which are about to be described. It is justly claimed by men of practical experience that laboratory tests on a small scale should not be used to draw sweeping deductions which may not accord with the results of experience, and may indeed even introduce into practice methods of doubtful value. While admitting the general truth of this argument, it may be claimed that careful and systematic experiments based upon a sound theory are sure to yield fruitful results. It is interesting to note that in so far as they are comparable these results show a striking agreement with the English experiments carried out in 1899 and described by Smith.*

In order to extend these investigations into the field of practice, 600 large plates, representing three kinds of steel, were mounted in wooden frames facing the sea-shore near Atlantic City, N.J. These plates were painted under the strictest test conditions with the single paints as well as with formulæ made up from the three tentative classes of pigments. The following organisations co-operated to a greater or less extent in this work:—United States Department of Agriculture, American Society for Testing Materials, Paint Manufacturers' Association of the United States, Master Painters' Association of Pennsylvania, Carnegie Steel Company and American Rolling Mill Company. The test plates, which were completed and exposed to the weather and salt air in September 1908, are being watched with interest, and it is hoped and believed that they will yield results of much value to the metallurgist, the engineer and to all persons interested in paint technology. In view of the fact that these tests have been described in detail in a preliminary report † of the scientific section of the Paint Manufacturers' Association, it is unnecessary to describe them further at this time.

If we apply the auto-electrolytic theory of the cause of corrosion to the subject of protection by paint films, it follows that in general pigments that are good conductors of electricity should never be applied directly to the surface of iron or steel. A moment's thought will serve to show why this must be true, provided the theory is true. It has been shown that the surface of iron or steel, when brought into contact with an electrolyte, tends to throw itself into positive and negative nodes, so that spreading out a good conductor on the surface in the presence of moisture and oxygen will tend to stimulate corrosion at the positive nodes with the well-known pitting or tuberculation effect always noted when steel rusts under atmospheric conditions. Whether the conductor is of the first class, such as powdered aluminium or graphite, or of the second class, such as a soluble inorganic salt, makes little difference, as either will stimulate the solution pressure of iron at the positive points. In the light of this theory let us consider the probable effect of using three forms of carbon pigments—lampblack, graphite, and willow charcoal—in contact with moisture on the surface of steel.

Of these three pigments in the dry state, lampblack and graphite have a high conductivity, while willow charcoal is almost an insulator. In order to get an approximate measurement of their relative conductivities in the moist state, 10 cubic centimetres of each of the three pigments was shaken up with 100 cubic centimetres of very pure distilled water, and the conductivity of the resulting slimes quickly measured in a special type of conductivity cell. The results obtained are shown in the following table:—

Results of Conductivity Tests of Three Pigments.

Name of Pigment.	Comparative Resistance.	Comparative Conductivity.
	Per cent.	Per cent.
Lampblack . . .	0·44	2·28
Graphite	1·10	0·91
Charcoal	1·83	0·54

It will be noted that in three out of the five experiments the corrosive action of the three pigments falls in this same order. In every case the lampblack and graphite appeared high up in the "stimulator" class, while willow charcoal just qualified as an "inhibitor." If we inquire why willow charcoal exhibits a slight conductivity when damp, and yet is to some extent an inhibitor of rust, the answer is that all charcoals contain a slight amount of potash. It is admitted that the conductivity test could not be generally used in order to determine the corrosive effect of a given pigment, for every-

Digitized by Google

thing must necessarily depend upon whether the material which passes into solution, and thereby increases the conductivity of water, is stimulative or inhibitive in action. Thus, alkaline electrolytes as well as chrome compounds inhibit, while acid and neutral salts generally stimulate corrosion.

Nevertheless, the test of the three carbon pigments as given above is of value, inasmuch as it indicates that good conductors should not be used in the first application to iron and steel, unless the conducting material is inhibitive in its nature. In order to determine whether or not this indication would be borne out by actual paint tests the following experiments were made:—The three carbon pigments were ground in the usual manner with a good grade of raw linseed oil and a small amount of a good drier. These three paints were then thinned slightly with pure turpentine and painted in neighbouring stripes on samples of very pure steel which had been machined and polished to a smooth surface. After the paint films were set the plates were laid flat and covered with damp blotting-paper, under which they were kept for three weeks. At the end of this time the paint films were removed with the usual paint solvents, and the surface carefully examined. The steel was deeply etched under the graphite, less so under the lampblack, and to a much less extent under the willow charcoal. During the course of this work it occurred to the writer that if an acceleration test could be devised to distinguish between inhibitive and stimulative pigments by a simple and easy method, and without the necessity of referring the matter to a chemist, it would be of great value to both manufacturers and consumers. To this end the following test has been devised:—

The pigments to be tested are rubbed up with sufficient water to make thick water-colour paints, and are then flowed or brushed upon the clean blades of steel table-knives. After the coatings are dry the knives are laid on a wet blotter and covered with a sheet of wet blotting-paper. At the end of forty-eight hours the surface is cleaned off with running water and a stiff brush. This acceleration test has been found to give results which agree with the oil-film tests. The following list indicates the pigments that were used:—

List of Pigments used in Acceleration Test.

No. of Knife.	Pigment.
Fig. 1 (1) . .	. Barium chromate.
„ (2) . .	. Zinc lead chromate.
„ (3) . .	. Zinc chromate.
„ (4) . .	. Lampblack.
„ (5) . .	. Graphite No. 2.
„ (6) . .	. Willow charcoal.
Fig. 2 (1) . .	. Zinc and barium chromate.
„ (2) . .	. Chrome green (blue tone).
„ (3) . .	. White lead (Dutch process).
„ (4) . .	. Red lead.
„ (5) . .	. Litharge.
„ (6) . .	. Ferro-ferric oxide.

These film corrosion tests usually agree with the results obtained in the Thompson test, and in the few cases in which differences have been noted reasonable explanations are forthcoming. For instance, in the cases of some of the very heavy pigments, such as the leads, barium compounds, &c., it was impossible in the air-bubbling test to keep them in suspension, with the consequence that the steel was in contact merely with the supernatant liquid. The damp film test is much easier and more rational than the bubbling test, and will probably come into very general use.

The fact has been brought out that some pigments which have been supposed to be excellent for protecting steel should in reality never be used, at least for the prime or contact coat, and that some pigments which theoretically should inhibit corrosion in reality appear to stimulate it. This is very well shown in the chrome pigments, some of which appear to be inhibitors and some stimulators, depending upon the technology of their preparation and whether or not they contain stimulating impurities.

As a result of a large number of these film-tests, the following conclusions appear to be justified, and are therefore advanced at this time:—

1. The name of a type of pigment does not necessarily guarantee its inhibitive value.

2. Pigments which are good conductors of the first class should not be applied as the prime or contact coating to iron and steel.

3. If pigments contain material which is even in the slightest degree soluble in water, they should not be used unless their inhibitive effect on corrosion has first been established by test.

The use of varnishes and bitumens on the surface of iron recommends itself on account of the well-known insulating properties of these materials. The author has succeeded in making a successful prohibitive lacquer by dissolving chromic acid crystals little by little in a filtered alcoholic solution of shellac. Many cases are on record in which pure refined coal-tar has given a good account of itself as a protective coating, and undoubtedly many of the proprietary bituminous paints and compounds are well adapted for application to iron. The reason that such materials are not in general use appears to be that they change their nature to some extent as they age, and are apt to become brittle, or to produce the effect known as "alligatoring" under the action of sunlight and the atmosphere.

Protection with Cements.

The question whether steel embedded in concrete is protected from corrosion is of the highest importance. If steel reinforcements rust away, it bodes ill for the future of many modern structures, owing to the impossibility of making inspections and repairs before the danger point is reached. The records of discussions before a number of engineering and scientific bodies show that there is conflicting evidence and opinion in regard to this subject. There can be no doubt that the reaction of unleached cement concrete is strongly alkaline owing to the separation of free lime at the time of set. If this alkaline reaction is maintained, steel embedded in the concrete should remain uncorroded. If, however, as is sometimes the case, percolating waters find their way through the concrete, the free lime will eventually be removed and dangerous rusting take place. Nails and other objects of steel will remain bright when immersed in lime water, and the author has found that the addition of about 5 per cent. of quicklime to soggy sour clays and soils will have a very decidedly protective effect on steel embedded in them. It is curious that this simple expedient has not been resorted to in order to prolong the life of steel pipe lines trenched in soggy clay soils where there is but little movement of soil and subsoil water. Cement paints and grouts have also been used to protect steel but have not come into general use owing to the difficulty in making them adhere without cracking and peeling off.

Processing after Manufacture to form a Coating of Oxide, Phosphide, Silicide, &c.

A number of metallurgical processes, such as the Bower-Barff * and others, have been from time to time proposed, and exploited for producing an oxidised surface on steel. As far as the writer is aware, none of these have as yet been found practically successful, except for certain special purposes.

The Coslet process is said to consist in immersing the iron in a hot, phosphorised solution containing an iron compound. The surface, it is claimed, is converted into a ferroso-ferric phosphate, which is to some extent resistant to corrosion. Joule † has called attention to the fact that iron containing 20 per cent. of silicon is not attacked by acids, and therefore such material should theoretically be unrustible. The author has confirmed this deduction by experiment, and found that iron containing 10 per cent. of silicon is almost incorrodible. Unfortunately, such a metal is not easily workable and has peculiar properties. Since silicon is much like carbon, chemically speaking, it would seem as if it might be worked into the surface of steel by modifications of some of the processes used for case-hardening with carbon. If anyone should discover a method for applying a skin of high silicon metal on worked steel it would be a contribution of the highest value to the art of metallurgy and to the world at large.

Unprotected Steel.

A very large proportion of the iron and steel which is in use cannot, from the very nature of the service to which it is put, be protected from corrosion. To this class belong rails, heavy chains, implements, boiler tubes, &c. The only hope of meeting this particular phase of the problem consists in the improvement of metallurgical processes, to the end that perfectly homogeneous metal, as free as possible from segregation, may be manufactured. It is well known that some of the alloyed steels, such as nickel steel, are very highly resistant to corrosion. The same thing is probably true of the chromium and chromium-vanadium steels. Unfortunately, such materials are too costly to be used on a large

* M. P. Wood, *Rustless Coatings*, 1905, p. 166.
† *Engineer*, 1908, vol. cvi. p. 397.

Digitized by Google

scale, although there is always the possibility that some alloy or combination will be discovered which will be at the same time comparatively inexpensive and incorrodible. It appears to be the opinion of a number of metallurgists with whom the author has corresponded that carefully made open-hearth steels, in which the ordinary impurities have been worked down to a minimum, with especial care in the heat treatment, are much more resistant to corrosion than the ordinary run of merchant steel. One well-known example of this type of steel which is on the market, and has already been referred to in a previous paragraph, has the following composition:—

	Per cent.
Sulphur	0.019
Phosphorus	0.004
Carbon	0.026
Manganese	trace.

This metal is therefore, practically speaking, 99.95 per cent. pure. Although it is apparent that a metal of this character could not be used where a tensile strength in excess of 40,000 lb. to 50,000 lb. per square inch is required, there are certain purposes for which it is well adapted, such, for instance, as roofing, sheathing, culverts, pipes, &c.

It has been found that this pure steel (or iron) resists the attack of acids to a high degree, and an acid test has been proposed to predetermine the resistance to corrosion of various types of metal. This proposal has, however, met with decided opposition from some metallurgists, who believe that the test is not a rational one. The need of a quick preliminary test for determining the resistance of steel and iron to corrosion is universally conceded. It is, however, in the opinion of the author, extremely doubtful whether such a test is possible, in view of the fact that the auto-electrolysis which is slowly but continually at work in the natural process of rusting, does not proceed in the same way in any short-time test. This criticism applies to all the various tests which have been proposed, such as immersion in corrosive liquids while air is being bubbled over the test-pieces. A considerable amount of work has already been done in investigating this particular problem, and the results have already been in part published.* More work is being done and will soon be published. Up to the present time there would seem to be but one perfectly sure criterion, and that is the test of service.

Electrolytic processes for protecting steel have also from time to time been proposed. As far as the author is aware, none of them have come into general use. It should of course be possible, by making the steel to be preserved the anode in an electric circuit against a scrap-iron cathode, to check, if not entirely stop, corrosion. It is, however, extremely doubtful if such a method could be made to work economically. Engineers are much disturbed by the damage to certain steel structures which is caused by electrolysis due to vagabond currents from high potential circuits used in lighting, trolley lines, &c. This undoubtedly constitutes a very serious engineering problem, but it should be remembered that extraneous currents may be made to protect as well as to attack steel through electrolysis. Laboratory experiments indicate, however, that a considerable voltage is necessary to prevent a steel anode in an electrolytic circuit from suffering from corrosion. The action which has been described in this paper as autogenous electrolysis, or auto-electrolysis, may be truly said to be the underlying and active cause of all forms of corrosion.

Conclusion and Summary.

It has been shown in this paper that the preservation of iron and steel has a direct and important bearing on the conservation of the natural resources of the world. The controlling factors which influence the more or less rapid corrosion of iron and steel are discussed in the light of the electrolytic or auto-electrolytic theory of rust formation. The various methods which are in common use, or which have been proposed for the protection of iron and steel, are then considered, with special reference to the results of recent investigations, and certain new principles are announced to serve as a guide in the selection of paints for the prime or contact coatings for steel. With regard to the protection of metal which, from the nature of its service, cannot be treated with a protective coating, it is pointed out that this is purely a metallurgical problem, dependent upon the manufacture of a perfectly homogeneous and carefully worked material.

* *Transactions of the American Society for Testing Materials*, 1908, vol. viii. p. 231.

LONDON COUNTY COUNCIL.

THE parliamentary committee report as follows:—

In Part V. of its General Powers Bill of the present session the Council is seeking powers, inter alia, to amend the London Building Acts with regard to buildings of metal skeleton framework. In this connection we have had before us a report by the Secretary of State for the Home Department on the Bill containing the following observations on Part V. of the Bill:—

Clause 30.—Provisions with respect to buildings of iron and steel skeleton construction.

"The Secretary of State observes that it is proposed, in paragraphs (31) and (32) of this clause, not only that buildings shall be constructed in accordance with the preceding provisions of the clause, but also that they shall be so constructed to the satisfaction of the district surveyor, and further, that any person dissatisfied with any requirement of the surveyor may appeal to the Council, whose decision is to be final. This procedure appears to the Secretary of State to be of very doubtful propriety.

"He would point out that by clause 32 the provisions of this part of the Bill and any regulations made thereunder are to be incorporated with Part VI. of the London Building Act of 1894, and that under section 200 of that Act every person who fails to comply with any of the provisions of Part VI. is made liable on summary conviction to a maximum daily penalty of 20*l.* during every day on which he fails to comply with the Order of the Court. Any failure, therefore, to comply with the provisions of the present clause would render the defaulter liable to a heavy penalty enforceable by criminal proceedings, and it would appear that the effect of paragraphs (31) and (32) would be to make the district surveyor in the first instance, and, secondly, the Council, the judges whether or not such failure had taken place, so that the only function of the Court before whom the defaulter was summoned would be to fix the amount of the penalty. The Court would, apparently, have no power of adjudicating on the case.

"It appears to the Secretary of State that in the case of summary proceedings for a criminal offence the question whether or not the offence has been committed ought to be decided by the Court. If on the other hand the committee are of opinion that the questions that may be raised under the present clause are of such a technical character that they cannot properly be dealt with by the ordinary Courts, he suggests that the proper course would be to give a direct appeal to a strong expert tribunal such as e.g. the Tribunal of Appeal under the Act of 1894, with special powers."

The Local Government Board also refers to this matter in its report on the Bill, stating that "it appears to the Board to be doubtful whether the appeal to the County Council proposed in this paragraph (i.e. (32)) is the proper method of dealing with differences between the district surveyor and persons affected by the clause."

We have had before us a deputation from representatives of the following societies, viz., the Institution of Civil Engineers, the Royal Institute of British Architects, the Surveyors' Institution, the Institution of Mechanical Engineers, the Concrete Institute and the Institute of Builders, urging that an appeal from the decision of the district surveyor to the Tribunal of Appeal should be allowed in such cases. We understand that the Building Act committee are in favour of an amendment of the Bill to provide for an appeal, but consider that the appeal should be to a Divisional Court. We feel, however, that such an appeal would involve great delay and expense, and the question to be decided would often be of such a character as could be most appropriately decided by experts. Moreover, technical difficulties might be raised against giving this jurisdiction to a Divisional Court, particularly if, as has been proposed, the Court were to sit with expert assesors in hearing cases of this class. Under the circumstances we have come to the conclusion that the best tribunal to appeal to would be the Tribunal of Appeal, which is already specially constituted by the Act of 1894 to deal with questions relating to buildings. The Tribunal consists of a barrister, an architect and a surveyor. It has been suggested that an engineer should sit with the Tribunal when appeals under this part of the Bill are heard, but we think it is unnecessary to provide for this as the Tribunal has already power to obtain such professional advice and assistance as it may find necessary. We regret that we have not been able to confer again with the Building Act committee before reporting to the Council, but there was no time to do so as the Bill was fixed for hearing before the select committee on June 21, 1909. We therefore recommend—

Digitized by Google

"That Part V. of the L.C.C. (General Powers) Bill, 1909, relating to buildings of metal skeleton framework, be amended to provide that there shall be an appeal from the decision of the district surveyor to the Tribunal of Appeal constituted under the London Building Act, 1894."

The Building Act committee report as follows:—

General line of buildings on the south-eastern side of Euston Road, between Duke's Road and Mabledon Place.

On November 17, 1908, the Council decided to take an appeal against the decision of the Divisional Court in the matter of the case stated by the Tribunal of Appeal with regard to the certificate of the superintending architect of metropolitan buildings defining the general line of buildings on the south-eastern side of Euston Road, between Duke's Road and Mabledon Place. The appeal was heard on April 22, 1909, and on May 14, 1909, the Court decided that the Council's appeal should be allowed, with costs in that court and the courts below. As stated in the report referred to above, the question at issue was whether the superintending architect of metropolitan buildings and the Tribunal of Appeal should take into consideration certain one-storey shops erected with the consent of the Metropolitan Board of Works, and others which appeared to have been erected unlawfully. In giving the decision of the Court of Appeal Lord Justice Fletcher Moulton stated that it was not competent for the superintending architect or the Tribunal of Appeal to take into consideration buildings which had been erected with the consent of the Metropolitan Board of Works or the Council under section 75 of the Metropolis Management Amendment Act, 1862, or by the Council under the London Building Act, 1894, and Lord Justice Farwell in support added that, in his opinion, the true presumption of law was that all the buildings erected in that part of Euston Road, which was the subject of the appeal, in regard to which no evidence could be found as to whether there had been a consent or not must be presumed to have been erected with the consent of the Metropolitan Board. The respondents have not yet decided whether they will appeal to the House of Lords.

OUR CONTEMPORARIES FROM OVER-SEAS.

THE *American Architect*, continuing its review of architecture in the Southern States, deals with Birmingham, Alabama, the Pittsburg of the South, of which city and its architecture there is a descriptive account with illustrations, principally of domestic work. An interesting feature of some of the Alabama homes depicted is the use of out-of-doors sleeping rooms, a feature that even in our own changeable climate is of some importance to architects, not only in the designing of sanatoria but of private residences, seeing that we have already amongst us some enthusiasts for fresh air who sleep without other roof than that of heaven—till a shower comes.

Der Profanbau should be of interest to competitors for the recently awarded Tite prize of the Royal Institute, as it is mainly occupied with an account and copious illustrations of an arcade of shops—Friedrichstrassen-Pazage—in Berlin, of which Kaiserlicher Baurat Ahrens is the architect. The detail would hardly do for the Tite prize, as it is far removed from "the principles of Palladio, Vignola, Wren, or Chambers," but the design is a virile and effective piece of architecture. An effective feature in the plan is a domed central hall, which greatly assists in overcoming the difficulty of a change of line necessitated by the want of parallelism in the two streets that the arcade connects.

Stone in its present issue changes its form, and we congratulate our contemporary on the improvement. It contains some excellent illustrations of stone buildings and workmanship, notably one of the entrance to the University of Toronto, built in 1859 from the design of Mr. W. G. Storm, which, based on French Romanesque work, is quite remarkable both as a piece of architecture and an example of well-preserved masonry.

The Engineering Record (New York) has an interesting article by Mr. Henry S. Spackman on the effect of calcium aluminate on mortars, in which he points out the possibility of giving to natural cements and limes slow-setting and quick-hardening properties resembling those of Portland cement, with the advantages of low cost, ease of manufacture and inexpensive works.

Het Huis has an article, fully illustrated, on old buildings in the island of Texel, the farm houses and cottages of which appear to be simple but eminently picturesque, almost entirely pan-tile roofed over a ground storey, with one or two storeys in the roof. There is in this number also a description of some of the Indian art work in the Batavian Museum.

Moderne Bauformen this month maintains its high standard, and in addition to views of modern German architecture deals with the work of Herr G. A. Bredow, of Stuttgart, a sculptor of the "new art" school, and also in an appreciative article, fully illustrated, with that of Mr. E. Guy Dawber.

Deutsche Bauzeitung continues its account of the work of Herr Philipp Kahm at the Schloss Vollrads, in Rheingau, to which it devotes all its illustrations.

NOTABILIA.

THE *Pall Mall Magazine* contains an article on Birmingham and its University, which in a rather sketchy fashion gives some particulars of the history of the University, and illustrates some of the features of working Birmingham by means of impressionist or "pictorial" photography. Of topical interest is an article on "Six Famous Holbeins," which are depicted, of course including the "Duchess of Milan." "Treasure-hunting in Egypt," by Arthur E. P. Weigall, Chief Inspector of Upper Egypt, Department of Antiquities, gives a vivid account of the difficulties of Egyptian exploration and, on the other hand, of the excitement of a fortunate find.

Correspondence.

[The Editor will not be responsible for the opinions expressed by Correspondents.]

How to Know Good Architecture.

SIR,—Kindly allow me to correct a printer's error which occurs in *The Architect's* report of my lecture on "How to Know Good Architecture" in the paragraph describing the entablature of the Parthenon, which should read "the triglyphs become with the drops a kind of *bracket*" not *bracelet*.—Yours faithfully,

G. S. AITKEN.

33 Castle Street, Edinburgh:
June 22, 1909.

GENERAL.

A General Meeting of the Concrete Institute was held on Thursday evening, the 17th inst., at the Royal United Service Institution, Whitehall, for the further discussion of the paper read by Mr. H. K. G. Bamber on May 27 on "The Setting Time of Portland Cement and Methods adopted for Regulating the Same." Mr. F. E. Wentworth-Sheilds, M.Inst.C.E., presided, and the proceedings were opened by Mr. Bamber reading a contribution to the discussion received from Professor Le Chatelier. The discussion was then continued by Messrs. W. F. Reid, F.I.C., W. Gilbert, M.Inst.C.E., A. O. Trechmann, G. Blyth, J. W. Plaister, J. W. Davis and Geo. F. Fenwick.

In the Art Section of the National Eisteddfod of Wales (sculpture) Miss Margaret T. Wedmore, of Oakland Road, Redland, has won the first prize for plaster model of a study of a head in relief, life-size. The competition was an open one, and the adjudicator was Mr. J. Havard Thomas.

The Purchase of Lord Leighton's early picture, "The Death of Brunelleschi," painted when he was twenty, and measuring 104 inches by 76 inches, has been concluded, and the work is now added to the permanent collection at Leighton House, 12 Holland Park Road, Kensington, W.

A Meeting of the general preliminary committee of the Scottish Exhibition of National History, Art and Industry was held in the Trades Hall, Glasgow. Mr. R. J. Walker, architect, submitted plans showing how the western portion of the West End Park, Kelvingrove, could be utilised without disturbing the trees. The plans met with general approval, and it was agreed to submit the scheme to the Corporation and ask them to grant the use of that portion of the park. The plans submitted show a large industrial hall for Scottish art industries, a large fireproof building for pictures and historical exhibits, a concert and pageant hall, and for representing a street in ancient Glasgow and a Highland village, in addition to sites for restaurants, &c.

The Wood Green District Council have decided to erect public baths at a cost not exceeding 8,000*l*. Architects experienced in this class of work are to be invited to submit competitive designs, and the Council is offering premiums of 50, 25 and 15 guineas for the first three placed in order of merit by the consulting architect of the Council.

Ripolin was placed above competition (Hors Concours), which means the Highest Possible Distinction, ∴ ranking above all awards. ∴

For 50 years we have specialised in the construction of Glasshouses, and our name is now regarded all over the country as synonymous with all that is latest and best in Glasshouse construction. Contracts are undertaken for the erection and heating of

CONSERVATORIES, WINTER-GARDENS, VINERIES,

and all kinds of Glasshouses. The most recent improvements in Ventilation, Heating, and internal fittings are introduced.

Plans and estimates will be sent free on receipt of particulars. Special attention is paid to carrying out the designs of Architects with care and accuracy. Write for Illustrated Catalogue, post free.

NOTICE TO ADVERTISERS.

Under no circumstances whatever can the Proprietors of this Journal guarantee alteration of copy if received after the first post on Tuesday mornings, and no proofs can be submitted if copy arrives later than first post on Saturday mornings.

EDITORIAL NOTICES.

In view of the many difficulties which are certain to arise in connection with the law, practice rules and procedure under the Workmen's Compensation Act, we have added to our staff A VERY EMINENT BARRISTER, who has made the subject a special study, and will be glad to answer in the columns of this paper any questions relating to the complicated matters arising from the provisions of this difficult Act. Our LEGAL ADVISER will further answer any legal question that may be of interest to our readers. All letters must be addressed "LEGAL ADVISER," Office of "The Architect," Imperial Buildings, Ludgate Circus, London, E.C.

The Editor will be glad to receive from Architects in London and the Provinces results of Competitions and Tenders and other particulars of Works in progress in which they may be interested.

No communication can be inserted unless authenticated by the name and address of the writer—not in every case for publication, but as a guarantee of good faith.

Correspondents are requested to make their communications as brief as possible. The space we can devote to Correspondence will not usually permit our inserting lengthy communications.

The authors of signed articles and papers read in public must necessarily be held responsible for their contents.

TENDERS, ETC.

**** As great disappointment is frequently expressed at the non-appearance of Contracts Open, Tenders, &c., it is particularly requested that information of this description be forwarded to the Office, Imperial Buildings, Ludgate Circus, London, E.C., not later than 2 P.M. on Thursdays.*

CALENDARS, &c., FOR 1909.

WE have received calendars from the Federated Employers' Insurance Association, 30 Cross Street, Manchester, who insure for contractors' risks and workmen's compensation. The Empire Typewriting Company.—The machines are made in Canada but the picture on the calendar is of a lady typist working at a window facing the Royal Exchange. Messrs. Merryweather & Sons, Ltd., have inserted photographs of the motor engines at Windsor Great Park and Aldershot Command, and a motor fire-escape built for Shanghai. Messrs. Harrison, Jehring & Co., printers, &c., give the remaining eleven months in small type on the page devoted to each particular month. Messrs. Arthur L. Gibson, Tower Street, W.C., have made their calendar a thing of beauty by devoting the greater part of the space to a broad panel painting, "The Country Road," by an American artist, Mr. E. Lamasure; its value is increased by the explanatory leaflet attached. The City of Winnipeg have issued a calendar for the purpose of attracting business men with capital; marginal notes are given concerning the progress of the city. The block calendar of Messrs. Douglas Young & Co., surveyors and auctioneers, Coleman Street, E.C., is fitted with a support so that it can stand on any desk or table, and each day has its own proverb. The Practical Electrician's Pocket-book and Diary has for twelve years pursued an eminently useful career. Its size really is such that it can be placed in the pocket, while its pages contain enough condensed information to last the student and practical man many months. It is intended primarily for the wireman, jointer, dynamo and arc lamp attendant and electrical workers of all grades. The latest edition contains additional useful matter.

Designers of, and Contractors for, Ferro-concrete Buildings, Steel Frame Buildings and Fireproof Floors and Partitions. Have a large staff of Engineers, whose experience is at your service, and fully equipped works. They are prepared to guarantee all their work. They have carried out many thousands of pounds' worth of contracts for leading Architects, including Telephone Exchanges, Hospitals, Banks, Hotels, Warehouses, Offices, Flats, College Buildings, Breweries, &c.

Fireproofing

They are specialists in Ferro Concrete, and own numerous Patents for various systems. They prepare specially designed schemes for each inquiry to meet requirements of Architects.—Patents include sound-proof floors, non-centering floors, and expansion blocks for obviating the danger of expanding concrete thrusting out the walls. Ferro-concrete Floors, Roofs and Walls prepared for shipment abroad ready for fixing. They quote the lowest possible prices consistent with the highest class of work. They will be pleased to receive your inquiries and give them their careful attention.

TRADE NOTES.

THE directors of the London and Lancashire Fire Insurance Company have, in consequence of their enlarged business arrangements, decided to make their Cardiff office a separate branch, working direct to head office. Mr. A. D. Goodwin will continue to have charge, with the title of "local manager."

MR. E. J. MCDONALD has been appointed branch manager of the Law Accident Insurance Society in Hull, in succession to Mr. Nicholson, who has resigned the position.

THE Wrexham Town Council have instructed the borough surveyor to prepare a new scheme for municipal slaughter-houses.

THE tender of Messrs. Jackaman & Sons, Slough, amounting to 6,500*l.*, for the construction in reinforced concrete of Section No. 3 of the Eastern Wharf, has been accepted by the works committee of Dundee Harbour Trust. Operations will be carried out on the Hennebique system.

MR. W. P. R. WILLOUGHBY, M.I.C.E., engineer to the Pontypridd District Council, and architect to the Pontypridd education committee, has received the appointment of Director of Public Works to the Government of Jamaica, at a salary commencing at 1,000*l.* per annum.

VARIETIES.

FIRE-RESISTING construction was required for only 39 per cent. of the building permits issued in 1907 by forty-nine leading American cities, the remaining permits being for wood structures.

THE West Riding education committee have adopted grants in respect of the erection and equipment of secondary schools as follows:—Doncaster secondary school, 17,556*l.* (including 4,356*l.* for site); Normanton secondary school, 8,250*l.*; and Penistone grammar school, 7,708*l.*

THE annual exhibition of the work of members of the Architectural Association of Ireland is now open at 15 South Frederick Lane, Dublin. There are about seventy-five exhibits, and these include water-colour and oil paintings, photographs and sketches in black and white.

THE house committee of Darnley Hospital recommend the joint hospital committee to construct the new smallpox hospital of brick and rough-cast, similar to the existing pavilions at Darnley, but with lighter walls, at an estimated cost, exclusive of sanitary appliances, heating, and furnishing, of 1,303*l.*

MESSRS. C. BRIGHTMAN & SONS, of Watford, have secured the contract for the erection of the new station at Watford in connection with the Watford and Euston Electric Railway. The work will be commenced at once, so as to be completed by January 1910.

THE estimated expenditure for which it is proposed to seek powers in the Oldham Corporation Parliamentary Bill is 568,350*l.*, made up of the following items:—Waterworks, 130,000*l.*; tramways, 22,150*l.*; motor-omnibuses and motor-cars, 16,200*l.*; street improvements, 200,000*l.*; and gas-works, 200,000*l.*

DUMBARTON public library committee have accepted estimates for the new Carnegie assisted library to be erected in Strathleven Place, where a fine site was procured from the Town Council. The total cost of the building, without equipment, will be 3,971*l.* 18*s.* 2*d.*, and all the tradesmen are local.

31,430*l.*, gave six houses in Chaucer Street, Mansfield, for use as almshouses for the benefit of deserving aged or infirm persons in the town connected with the building trade.

AN adjourned meeting of the Council of the Northumberland Miners' Association was held recently, Mr. Joseph English presiding. It was decided that the resolution adopted last year with the object of preventing hewers from doing stone work should not be generally applicable. Hewers may be employed to remove stone in places where a greater height is required, and also in drifts and bargains.

THE Chester Race Company have informed the improvement committee that on a fourteen years' extension of the present lease they are prepared to carry out a reconstruction of the Dee stands, Roodee keeper's lodge, new private dining-room, store-room, &c., on the plan submitted to the committee, and arrange all the financial obligations in connection with the scheme.

PROSPECTS in the Transvaal have slightly improved, but much depression still exists, and there is no opening for more labour. An agreement has just been entered into between the Master Builders' Association and the various trade unions connected with building, fixing for two years the rates of wages, conditions of labour and the method of settling disputes.

THE contract for alterations and additions to the Central Post Office at Dudley has been given to Messrs. John Barnsley & Son, Birmingham, and the work will be commenced forthwith. The Dudley Town Council have agreed to contribute 400*l.* towards the cost of the undertaking, which is estimated at about 6,000*l.* The building is to be heightened by the addition of a storey and extended to Priory Street.

SIR ACHESON M'CULLOUGH, medical inspector, and Mr. P. C. Cowan, chief engineering inspector of the Local Government Board, have concluded the inquiry directed to be held by the Local Government Board into the application by the Belfast Corporation for a loan of 112,300*l.*, for the purpose of carrying out a scheme of better purification of the sewage of the city, and completing the Sydenham and Knock drainage scheme. Mr. R. I. Caldwell was the last witness.

THE Local Government Board has sanctioned an expenditure of over 11,000*l.* for the improvement of the Bridlington water scheme and waterworks. The committee have considered nine tenders for the necessary building work in connection with it. The tender of Mr. F. Kneeshaw, Bridlington, 2,505*l.* 17*s.* 9*d.*, is recommended for acceptance. The surveyor's estimate was 2,656*l.*, and the highest tender is 2,994*l.*

PLANS have been passed by the Great Western Railway Company for extensions at Exeter, which will practically involve the rebuilding of St. David's Station. The roof is to be removed and replaced by verandahs, and the station widened for additional up and down through lines. The two central platforms, 800 feet long, are to be widened, and new waiting and refreshment rooms are to be built on the island platform. The work will commence next month. Over 200 trains pass through the station every day.

THE Marylebone Borough Council at its last meeting discussed at great length a proposal of the electric supply committee that the main streets of the borough be lighted by electricity instead of incandescent gas as at present, and that application be made to the London County Council for a loan of 10,000*l.* to defray the cost of the alteration. Strong opposition was raised to the proposal, and further discussion on the subject was adjourned until the next meeting of the Council.

AT the Penistone district education committee meeting Mr. Stewart, from the West Riding architect's office, attended, and stated that the county education authority had decided to erect a school for Silkstone township at Conn Lane. They requested the committee to determine whether the school should be of corrugated iron or of stone and brick. The committee decided by six votes to four in favour of the county committee's proposals, and recommended that the school should be built of stone and brick.

THE Edinburgh Corporation and the Exhibition Executive have arrived at a settlement in connection with the restoration of the ground at Saughton. The Corporation are to be entrusted with the work of restoration on the payment of a lump sum by the executive. The sum agreed upon is 4,000*l.*, and in addition a sum of 400*l.* is to be allowed for a band-stand, the city retaining in addition the conservatory or

winter garden. All the erections on the ground at present will be removed by the exhibition authorities, and after this is done the work of restoration will be begun.

MR. ALLAN STEVENSON, district surveyor, has submitted to the sub-committee on the Loch Braden water scheme a detailed report as to the distribution of the 500,000 gallons of water to be supplied from the Loch Braden scheme to eighteen small towns and villages, as well as mansions and farms in the district. Assuming that Auchinleck and Ochiltree were included, the daily quantity required for towns and villages would be 385,180 gallons. The total cost for piping, including Auchinleck and Ochiltree, was estimated to be 17,229*l.* 18*s.*, and excluding Auchinleck and Ochiltree 12,172*l.*

THE Westminster City Council a year or two ago discussed the advisability of trying Sir Oliver Lodge's system of dissipating fog by means of electricity, but did not carry out the experiment, as they did not feel justified in expending the ratepayers' money. The Council has received a letter from Mr. E. L. Walford, of 47 Hamilton Terrace, N.W., stating that he proposes to get a small syndicate to subscribe money to try the experiment on a practical scale, and asks whether, if he is successful in obtaining the required sum, the Council will allow him to try the experiment in Westminster upon land the property of the Council.

NEGOTIATIONS are proceeding between the Stretford Urban Council, Lancs., and the trustees of the late Mrs. Rylands's estate for the purchase by the former of the town hall and baths at Stretford. The building was erected over twenty years ago by the late Mr. John Rylands and given over to the Urban Council on lease at a rent of 5*s.* a year. It had been hoped that the premises would be left unconditionally to the township on Mrs. Rylands's death, but as no mention was made in her will to this effect the trustees have found it incumbent on them to realise on the building. The sum required for it is understood to be between 8,000*l.* and 9,000*l.*, but this is regarded by the Council as excessive, and an offer has been submitted for a smaller amount.

PRELIMINARY work in connection with the new range of offices in the North Yard, Devonport, has commenced. The old entrance to the interior of the tower which abuts on the structure about to be demolished is being built up, and a new entrance made, which will give access to the stairway leading to the residences, &c., adjacent to the R.N.E. College. The new offices, which are estimated to cost over 20,000*l.*, will provide accommodation for the Admiral-Superintendent and the heads of departments and their staffs. The offices will occupy a commanding and central position, in close proximity to the train terminus, and directly in line with the principal landing place at the North Yard.

THE Corporation of Southampton having applied to the Local Government Board for sanction to borrow money for the purchase of a motor-car for the use of the borough engineer (Mr. J. A. Crowther), an inquiry was held by Mr. F. H. Tulloch last week. At the outset the town clerk intimated that the application for sanction to purchase a motor-car would not be proceeded with, as the firm who were to have supplied the car declined to allow it to remain on trial for a week, and without this understanding the Council refused to complete the bargain.

THE proposed erection of a house refuse destructor at Dorking, for which a loan of 3,225*l.* is necessary, was the subject of a long Local Government Board inquiry last week. Counsel appeared both for and against the proposal, the Dorking Water Company objecting to the site, which adjoins their reservoir, and a large number of ratepayers objecting on the ground of no present necessity .The Rural Council protested against the refuse from the urban district being dumped down in their district.

THE construction of the upper and lower Brush Quays for the Yarmouth Port and Haven Commissioners is to be carried out by contract. At the last meeting the chairman of the executive committee said the committee were of opinion that it would be advisable to put the work in the hands of contractors, in order that it might be done quicker. Their own employés could do the work, but it would take them five years, whereas if they placed the matter in the hands of contractors they would get it done in two years. It would mean a probable expenditure of about 28,000*l.*

AT the South-Western Police Court the County of London Electric Light Company were summoned, at the instance of the Wandsworth Borough Council, last week for contravening a prohibition order which required them to abate a nuisance arising from the issue of black smoke from their

THE "DRAWWELL" GRATE

Digitized by Google

chimney-shaft at Wandsworth. The company, it was said, had spent 2,000*l.* in securing the best possible appliances, but the issue of smoke occasionally was unavoidable. In this instance the issue only continued for five or six minutes. Mr. W. W. Young, supporting the summons, said the maximum penalty was 40*s.* a day. A penalty of 20*s.* was imposed.

AT Dartmouth Police Court last week Mr. Thos. W. Joyce, borough surveyor, was summoned for obstructing the highway. The obstruction was caused at South Town in consequence of an auction sale on the highway of firewood removed from three old houses which were then in course of demolition for the purpose of street widening. The Surveyor contended that the summons ought to have been served on the local authority, and not upon himself. The Chairman said the Bench found that the surveyor had committed a technical offence, and the majority of the Bench had decided to impose a nominal fine of 1*s.* and costs. The Bench were of opinion, further, that the Corporation had acted in good faith. The total amount of the fine was 12*s.*

A NEW china clay kiln has just been opened at Charlestown, St. Austell. The kiln is 380 feet long and 18 feet wide, and has a shed capacity for 10,000 tons. There are six large tanks adjoining the kiln, which when filled contains about 8,000 tons in its nica or raw state. The stack, which has been built of Pentewan concrete blocks, is 120 feet high. The fires were first lit on Saturday at noon. The clay will be conveyed in its liquid state to the new kiln through a deep granite adit from Carclaze, one of the oldest pits in the county. In the completion of the work it is estimated that 12,000 tons of stone have been used, 3,000 tons of sand, and over 300 tons of cement.

MR. HENRY CHAPMAN, M.I.C.E., M.I.M.E., civil engineer, chairman of the General Hydraulic Power Company, Ltd., deputy-chairman of the Employers' Liability Assurance Company, Ltd., an officer of the Legion of Honour, who died on October 8, aged seventy-three years, left estate valued 187,464*l.* 11*s.* gross, with net personalty 185,606*l.* 9*s.* 5*d.* He bequeathed to his Paris manager, Henri Vaslin, if still in his service, 1,000*l.*, and the goodwill of his business at 10 Rue Lafitte, Paris, and 91 Boulevard du Nord, Brussels, stock, plant, and furniture, but not the benefit of existing contracts and book debts. To his London manager, Arthur Henry Hernu, if still in his service, he left 1,000*l.*, and his London engineering business at 69 Victoria Street, S.W., with stock, plant, and furniture, but not the benefit of existing contracts and book debts.

THE Nottingham Corporation have approved plans for the erection of a Wesleyan Institute adjoining the Albert Hall, which is in course of construction. The building will have four storeys and a mezzanine floor. On the ground floor there is to be a gymnasium about 47 feet square, a large reading-room, a billiard-room for three tables, a coffee lounge, a kitchen and offices. The whole of the accommodation here is to be utilised for the social side of the life of the men and boys. On the first floor there is to be a hall capable of seating 500, a crush hall and office rooms. On the second a large parlour, practically 40 feet square, and five other rooms of varying sizes for club purposes. There are to be four rooms of different sizes on the mezzanine floor and eight on the third floor. The cost is estimated at 32,000*l.* Mr. A. S. Lambert, of Nottingham, is the architect.

THE London County Council on November 26, 1907, authorised the employment until March 31, 1909, of clerks of works in the architect's department, to supervise the erection of working-class dwellings and other work on housing estates. The expenditure sanctioned was limited to a sum not exceeding 24*l.* a week, but it is estimated that the amount required for similar services during the ensuing financial year will not exceed 16*l.* a week. The establishment committee recommend that, subject to the passing of the estimates for the unestablished staff of the architect's department for the financial year 1909-10, weekly expenditure not exceeding the undermentioned amounts for the employment of assistants on the unestablished staff in the several sections of the architect's department for the year commencing April 1, 1909, be sanctioned:—Building Act section, 46*l.*; means of escape section, 11*l.*; improvements section, 25*l.*; establishment and fire brigade section, 50*l.*; housing section, 50*l.*; general section, 50*l.*; highways section, 30*l.*; measuring surveyor's section, 55*l.*

Court. It was brought at the instance of the Master of Works, Mr. Thomas Nisbet, against Messrs. Aikman & Thomson, in respect of property in Henderson Street, the windows of which, Mr. Nisbet complained, are not so constructed as to be capable of being cleaned from the inside of the apartments. The case was debated before the Dean of Guild, Mr. M. Pearce Campbell. At the debate the Dean of Guild stated that he would visit the property and inspect the windows. This visit took place, and in presence of the Dean and other officials there was an experimental cleaning of the windows from the inside. The case was again on the roll of the Court on December 24, when it was intimated on behalf of the Fiscal that he did not desire to add anything to his previous argument. Accordingly the matter was left to the consideration of the Court, parties being asked to lodge a joint minute setting forth the dimensions of the windows. The decision is expected shortly.

THE Staffordshire education committee have adopted the works sub-committee's recommended acceptance of the tender of Messrs. G. Cave & Son, of Wolverhampton, of 8,786*l.*, for the erection of a Council school at Albion Street, Willenhall, to accommodate 1,090 children. The following other estimates were also accepted:—Messrs. W. H. Manley & Co., of Penn Road, Wolverhampton, installation of low-pressure hot-water heating apparatus, 543*l.*; Messrs. Lea, Son & Co., Ltd., Shrewsbury, electric lighting throughout, 224*l.* 4*s.*; Midland Electric Corporation for Power Distribution, Ltd., of Birmingham, providing and laying electric service cables, 19*l.* 0*s.* 5*d.* The County Council were recommended to provide 11,000*l.* for the proposed school. The tender of Mr. F. J. Tooby, of Wolverhampton, for 3,673*l.*, for the erection of Bushbury Lane proposed Council school, and that of Messrs. Manley & Co. for installation of heating apparatus, for 192*l.*, were accepted. The County Council were recommended to provide 4,700*l.* It was resolved to purchase 5,536 square yards of land, at 1*s.* 6*d.* per square yard, from Mr. M. Farmer, as a site for Essington new Council school, and two freehold cottages in Tenterbanks, Stafford, from Mr. E. Price, of Walton, near Stafford, for 250*l.*, for the purpose of providing additional site for the proposed Council school in Tenterbanks. Amended sketch plans for Darlaston proposed handicraft centre were submitted by the architect and approved.

S. H. BENSON, LTD.

No. 1 Tudor Street has for ten years been occupied by Benson's, one of the leading advertisement agencies in London. The firm have now moved into more prominent quarters at Kingsway Hall, W.C., on the great Holborn to Strand thoroughfare, where the upper floors have been constructed to their special needs. Perhaps another indication of improvement is in their new designation as "Professional Advertisers." S. H. Benson, Ltd., have in the past achieved numerous triumphs, the benefits of which are enjoyed by their clients; these must number many thousands, for some of the largest companies have entrusted the advertisement of their commodities to this firm. It might perhaps be hinted by some that they have done their work too well, inasmuch as it is difficult to escape the outdoor advertisements of certain soups, soaps, mustard, meat extracts, &c. Kingsway Hall can be located from either the Strand or Holborn by a lofty dome surmounted by a time ball. The entrance is immediately under the dome. The offices are reached by a private lift, and will in a few weeks shelter all the departments of Messrs. Benson, which should be able to do still better work in their new premises.

THE Coventry City Council on Tuesday considered a report of the general works committee on schemes for municipal buildings, including a town hall, &c., on the cleared site in Earl Street. The city engineer (Mr. Swindlehurst) had prepared sketch plans showing how the land could be utilised—the offices to face the front of the street and going down St. Mary's Street, with a town hall located at the western end of the street and Hay Lane. The matter was eventually adjourned for a month.

THE Edinburgh Dean of Guild Court have granted a warrant to the United Free Church General Trustees for the erection of a building for their offices at 119 and 121 George Street, Edinburgh. The building, which is of four storeys, includes a basement with store cellar and strong room, while shops will occupy the street level. On the first floor will be the Presbytery hall, committee room and clerk's offices; and the second floor will include luncheon and smoke rooms.

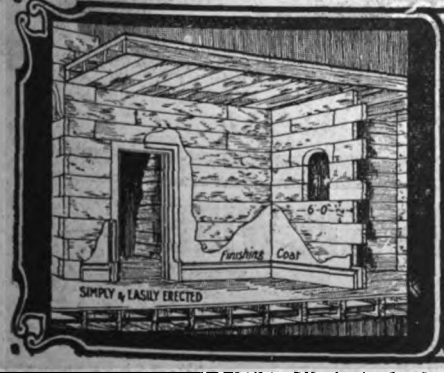
ABERDEEN WATER SUPPLY.

DR. MATTHEW HAY, medical officer of health for Aberdeen city, referring to the city water supply in his annual report to the Town Council, quotes from a report which Professor Hamilton and he prepared for the water committee, in which they stated:—"We may remind the committee (water committee) that, at their request, we made an examination, in the autumn of 1906, of some of the sources of domestic pollution of the river Dee. We have also seen the report prepared by the burgh surveyor on the subject, with the accompanying map, showing numerous points of pollution—actual or possible—of the river from the Invercannie intake upwards, and we are satisfied that it is not practicable effectually to guard against dangerous pollution at all these points and at all times. In view, therefore, of the results of our examination of the water supply, and of our knowledge of the impracticability of adequately protecting the river against domestic pollution, we have no hesitation in expressing the opinion that the water supply of the city in its present condition is dangerous, and that steps should be taken either to filter the water or to obtain a supply from a source not open to domestic pollution. Filtration of the present supply is, in any case, advisable in order to remove the turbidity which is so frequently observed after wet weather."



Continuing, Dr. Hay says:—This report serves to confirm the opinion I have frequently expressed in my annual public health reports regarding the unsatisfactory, and even dangerous, character of the present water supply so long as it remains unfiltered. The towns are quite exceptional in which a similar supply is drawn without filtration from a river open to the same kind and extent of pollution as the Dee. It may not be held to fall within the province of the medical officer of health to express an opinion upon the recent proposals for the provision of a purer and more ample water supply for the city, especially when these proposals have assumed a somewhat controversial character; but, having recently visited, along with the Town Council, the source of a proposed new supply in the river Avon, and knowing something of the nature of its gathering ground and of the character of the water, I cannot refrain from expressing the opinion that the city would be highly fortunate if it were found practicable to obtain a new supply from such a source. The water is obviously one of great natural purity, and so placed as to be beyond the possibility of dangerous contamination, and the best of all waters is one—like this of the Avon—of such natural purity as not to require filtration. Such a water is more wholesome and safer hygienically than a contaminated water purified by filtration.

PANAMA CANAL CONTRACTS.

THE news that the Lunkenheimer Company, of Cincinnati, Ohio, U.S.A., have just received an order for some 7,000 valves, in sizes ranging from ¼ inch to 3 inches, in connection with the work on the Panama Canal, reminds us of some of the enormous contracts given out in America when this work was first undertaken by that country. The days of the French régime were looked upon as times of extravagance as regards supplies, but it appears that in more recent times others have not been altogether free from fault in this respect. For instance, when Chief-Engineer Stevens took up his appointment he found 3,000 cases of stores at the Isthmus without names or destination, and his first efforts were directed towards sorting and allocating these supplies. From eight to sixteen per cent. of the men employed were at one time engaged in receiving and handling the stores. Up to 1906, some 262,420 pairs of butt and strap hinges had been ordered and supplied to the Canal works; also 70,992 files, in equal numbers of all sizes, from 4 inches to 14 inches; 530 tons of lead were supplied for one year's painting, which entailed the employment of one painter for every fifty men at work in the Isthmus. No less than 100 rail-saw machines were ordered in April, 1905, the size of this order being largely accounted for by the necessity of constantly relaying the working tracks. Another order of some size was one made up of several for bolts, screws, &c., altogether amounting to about 4½ million bolts, from which it would appear that the American steam-shovels and other plant in use at the Isthmus shed bolts and nuts about as freely as balsam distributes its ripe seeds on a hot day. In the above it may be noted that at the time the contracts for hinges were given out there were only some 1,222 buildings under the control of the Canal authorities, though this number has now been

doubled. Even so, however, the figures suggest something more than lavish provision, taking into account hinged mosquito screens in addition to doors and windows, &c. Of files it is quite unusual to order equal numbers for all sizes, some sizes, as a rule, being much more in demand than others. Then, again, we hear of thousands upon thousands of hand-saws, and of every other item all through hardware or ironmongery catalogues. In his book "Retrieval at Panama," Mr. Lindon W. Bates takes up this question and shows that on official statements the consumption of stores at Panama has been enormous. It was once officially stated that a stock of stores valued at $1,200,000 was equivalent to no more than a thirty-five days' supply. Mr. Bates figured it out that at this rate materials and supplies alone from 1907 to the completion of the Canal project would cost the United States over $115,000,000, not to mention the amount already then spent.—*Engineering.*

AMALGAMATION OF GREAT NORTHERN, GREAT CENTRAL AND GREAT EASTERN LONDON RECEIVING AND BOOKING OFFICES.

THE Great Northern, Great Central and Great Eastern Companies announce that on and from January 1 the undermentioned duplicate booking and receiving offices in London will be closed, and the business transferred to adjacent offices as under:—

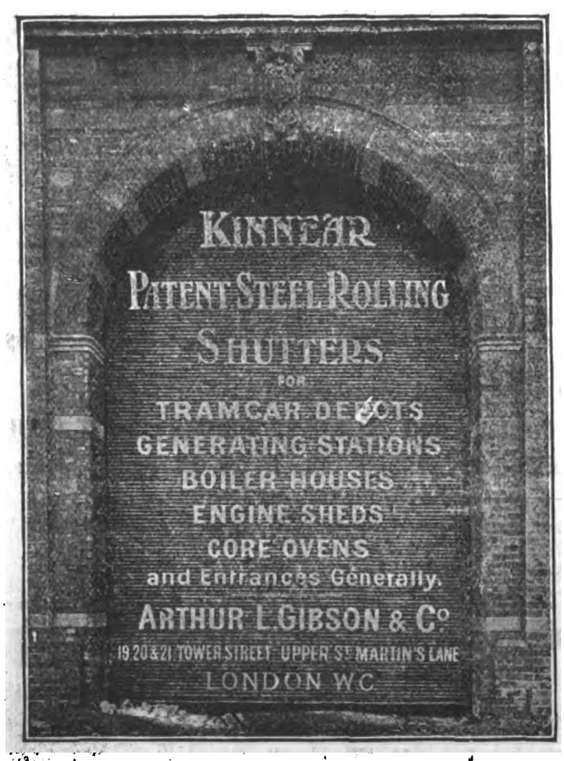
G.N. Office, 80 Bishopsgate Street, transferred to G.E. Office, High Street, Shoreditch and G.N. Office, 235 and 237 Old Street.

G.E. Office, 215 Edgware Road, transferred to G.N. Office, 169 Edgware Road.

G.E. Office, 353 Upper Street, Islington, transferred to G.C. Office, 341 Upper Street.

G.C. Office, 105 and 107 High Street, Borough, transferred to G.N. Office, "George Inn," and 75 High Street, Borough.

G.E. Office, Magnus House, Monument Square, transferred to G.C. Office, Dalmeny House, Monument Square.



G.E. Office, 120 Brompton Road, transferred to G.N. Office, 126 Brompton Road.

Also on and from January 1 the present Great Northern and Great Central joint booking and receiving offices, and the majority of the Great Northern, Great Central, and Great Eastern booking and receiving offices in London now separately owned will come under the management of the three companies, and these offices will, with one or two exceptions which will be notified, all deal with matters connected with the issue of passenger tickets, the collection and forwarding of goods and parcels traffic on behalf of the Great Northern, Great Central and Great Eastern Companies.

Passengers between London and the North have for the one fare the advantage of alternate routes when booking by either the Great Northern, the Great Central and the Great Eastern Companies.

THE new scheme for the building of a pier and casino at Brighton is to be strenuously opposed. The committee, consisting of persons with interests on the sea-front and in the town, which so strenuously opposed the late scheme for a summer and winter palace, decided at a meeting at the Royal Pavilion recently, to oppose the new proposal. The resolution also suggested the desirability of considering the propriety of forming a permanent association which might be prepared to take the initiative in opposing any future attempt to interfere with the rights of the public in the foreshore.

THE East Anglian Cement Company, whose offices are at Cambridge, have leased twenty-seven acres of land between Rushall and Aldridge, and in close proximity to the borough, with a view to the establishment of new works. Plans for the latter have been submitted to the Walsall Rural District Council, and experimental operations have already been commenced by a staff of workmen. The proposed works will be in close proximity to some extensive limestone workings. The whole district is noted for its limestone, and it is believed that a seam can be worked which will provide a valuable material for cement making.

WARING'S

(WARING & GILLOW, LTD.)

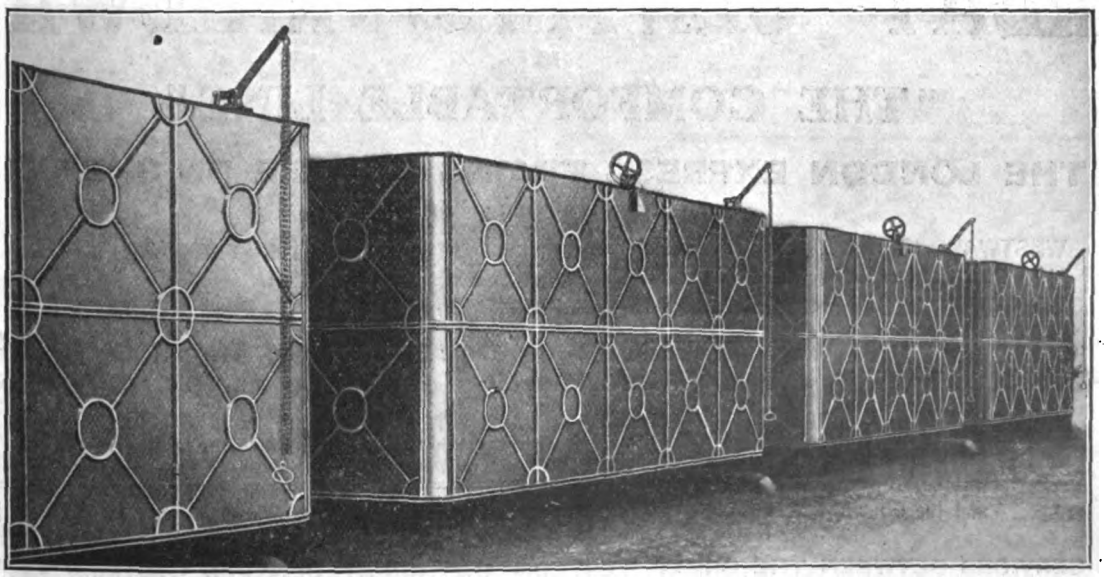
Beg to intimate that they are prepared under the personal direction of Architects, to

BUILD, ALTER OR ENLARGE

Hotels, Public Buildings, & Town & Country Houses of any size.

The feature of their Constructional Work is Soundness and Stability, combined with Rapidity of Execution.

In Waring's vast New Building, recently opened, there are Departments for everything in connection with either Contract or Private Work, and Architects may be assured that their wishes will be faithfully and carefully carried out by efficient workmen under expert supervision.



Waring's manufacturing resources enable them to satisfy Architects' requirements at the lowest tender prices.

NEAR OXFORD CIRCUS, LONDON.

ALSO AT LIVERPOOL, MANCHESTER, AND PARIS.

Safety in Woodworking

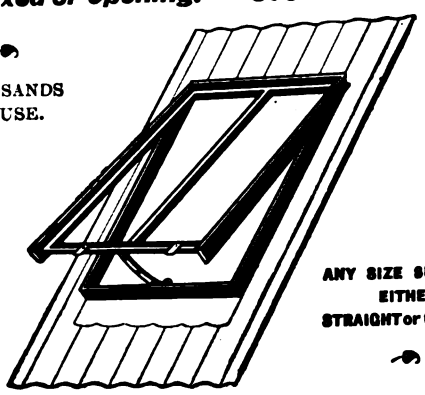
BRUSHES, Ltd., Brush Manufacturers, St. Albans, Herts.

"The Circular Block with which you supplied us has made quite a new machine of our surfacer, and the fact of the risk of accident being minimised gives the operator confidence, enabling him to produce more work. We think it speaks well for this invention when we say that, following out our usual practice of planing the stocks of our brushes on which backs have to be glued, the best class work which requires most care to secure good contact and neat finish is done on your machine. To put it in a nutshell, your Safety Cutter Block does better work with the least possible risk, and we are turning out better brushes than ever."

From J. PATERSON & SON, Builders, &c., Soho Street, Liverpool.

"Dear Sirs,—We can testify to the utility of your 'Patent Safety-Cutter Block,' which gives very superior work. Our machinist, using the Planing Machine, has just had a slip through a knot causing a break in a length of thin timber; the result, however, is that only the tip of one finger is injured. With the old cutter block and a similar accident, our man is quite sure that the whole of the fingers on that hand would have been destroyed. We feel very grateful to our district Factory Inspector for recommending this cutter block to us.

Yours truly, J. PATERSON & SON.



"P.S.—We are very pleased also with your 'Ideal' Saw Guard."

THE

Festiniog District Slate Quarry Proprietors' Association

THE Members constituting this Association, whose names are subjoined, beg to notify Architects and the trade that they are the producers of the genuine **Portmadoc Slates,** and would respectfully invite co-operation in discouraging the sale of other, and inferior, slates as such.

¶ The Members will be pleased to supply Acid, Water and Breakage Tests, with full Analysis; also a list of important Government and public buildings upon which their slates have been used during the past 100 years.

¶ Portmadoc Slates contain, according to analysis, only **1** per cent. of lime, whereas the imitation composite slates, now extensively advertised, show much variation; samples recently analysed contain upwards of **40** per cent. of this highly perishable substance, and are liable to an absorption of moisture **forty** times as great as that of Portmadoc Slates.

CHURCH AND PUBLIC CLOCKS.
Makers of Clocks and Chimes for St. Paul's Cathedral, Beverley Minster, Truro Cathedral, Thurles Cathedral, Belfast Assembly Hall, and many others to Lord Grimthorpe's designs.
In 1897, writing to Vicar of Minchinhampton, Lord Grimthorpe said: "Smith of Derby will clock you in the best way and as near eternity as possible."

BEST CURE FOR
SMOKY CHIMNEYS.

BY ROYAL WARRANT to HER MAJESTY the LATE QUEEN VICTORIA.
PATRONISED BY THE NOBILITY THROUGHOUT THE KINGDOM.

MILBURN'S PATENT
NOISELESS
REVOLVING CHIMNEY COWL.
NORTHUMBERLAND WORKS, MARLBOROUGH.

THIS is the only Cowl as yet in the market which in ALL cases prevents wind blowing down Chimneys. It is almost impossible to say too much in its praise. Placed in the most trying situations, it has never been known to fail. Great care is used in the construction of its internal fittings, which, being made of Copper and Brass, will last a long time. It is not at all liable to get out of order, and is made so strong that it will stand the force of a hurricane; in fact, increased action of a storm only increases its efficiency. It is perfectly noiseless; is easily swept—the shaft being free from obstruction to the sweep machine—the head cleansing itself; a heavy fall of snow does not impede its action, neither is it affected by frost. In case of the chimney taking fire it would remain uninjured, being made fireproof; and the oil-box requires replenishing with oil only once in six years.

Made in Galvanised Iron, with Copper Fireproof Oil-Box, £3 10s.

DELIVERED FREE to any Railway Station in the United Kingdom.

CAN BE FIXED BY ANY BUILDER.

THIRTY-SEVEN THOUSAND IN USE.

NOTE.—This Cowl has no Archimedean Screw which prevents Sweeping.

The Hammam
— ESTABLISHED 1862. —

FINEST AND MOST UP-TO-DATE TURKISH BATH IN EUROPE.

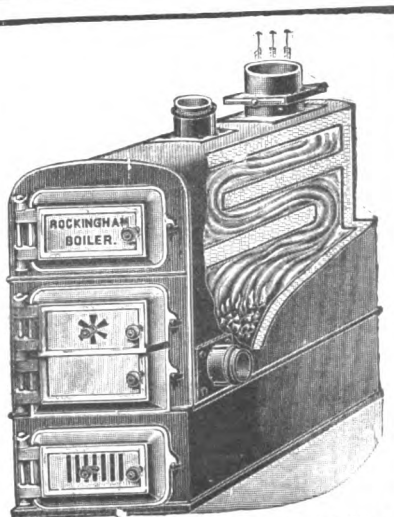
SAVE 50 %
OF YOUR
COAL BILL
BY USING THE PATENT
"BOND" STOVE

Recent Testimonial.

DEAR SIRS,—The heat it throws out is enormous, and it does not burn a quarter of the coal we have hitherto been burning.
T. BROWN (Doctor).

Also by using the Patent
"SINE QUA NON"
KITCHEN RANGE.

Recent Testimonial.



DEAR SIRS,—The Range is a complete success. It is an extremely good cooker, and heats the water for bath, lavatory, &c., perfectly, and I am quite sure the consumption of coal is not *half* as much as that burnt by the old range.
W. W. HARRIS.

These unsolicited testimonials, with many others, may be seen at, and Catalogues obtained on application to, the

Scagliola Marble

An old Italian process, revived in the early part of the Sixteenth Century by Guido Sassi; is not a surface decoration, but a thoroughly artistic material. It was largely used by the Florentines in some of their most elaborate works, and was introduced into this country by Mr. J. Wyatt about 1750. It has been manufactured by this firm for the last 85 years, and fixed in many of the most important buildings in the Kingdom.

BY SPECIAL APPOINTMENT
TO HIS MAJESTY.

SPÉCIALITÉ for surrounding Iron or Brick Cores.

These being fixed in the ordinary course of construction the SCAGLIOLA can afterwards be fixed round WITHOUT SHOWING JOINT.

Prize Medals, 1851 & 1862.

NOTICE TO ADVERTISERS.

Under no circumstances whatever can the Proprietors of this Journal guarantee alteration of copy if received after the first post on Tuesday mornings, and no proofs can be submitted if copy arrives later than first post on Saturday mornings.

EDITORIAL NOTICES.

In view of the many difficulties which are certain to arise in connection with the law, practice rules and procedure under the Workmen's Compensation Act, we have added to our staff A VERY EMINENT BARRISTER, who has made the subject a special study, and will be glad to answer in the columns of this paper any questions relating to the complicated matters arising from the provisions of thi difficult Act. Our LEGAL ADVISER will further answer any legal question that may be of interest to our readers. All letters must be addressed "LEGAL ADVISER," Office of "The Architect," Imperial Buildings, Ludgate Circus, London, E.C.

The Editor will be glad to receive from Architects in London and the Provinces results of Competitions and Tenders and other particulars of Works in progress in which they may be interested.

No communication can be inserted unless authenticated by the name and address of the writer—not in every case for publication, but as a guarantee of good faith.

Correspondents are requested to make their communications as brief as possible. The space we can devote to Correspondence will not usually permit our inserting lengthy communications.

The authors of signed articles and papers read in public must necessarily be held responsible for their contents.

TENDERS, ETC.

**** *As great disappointment is frequently expressed at the non-appearance of Contracts Open, Tenders, &c., it is particularly requested that information of this description be forwarded to the Office, Imperial Buildings, Ludgate Circus, London, E.C., not later than 2 P.M. on Thursdays.*

WE have received a request from Mr. J. N. Milner, the Oneida Community, Ltd., Oneida, New York, to supply him with a list of fireproof-window manufacturers in this country.

TRADE NOTES.

UNDER the direction of Messrs. Singer Hyde & Son, architects, Worthing, the "Boyle" system of natural ventilation, embracing the latest patent "air-pump" ventilators, has been applied to Christchurch schools, Worthing.

A LARGE clock has just been erected in the tower at the Public Park, Tunstall. It has four large dials, and strikes the hours. The work has been carried out by Messrs. John Smith & Sons, Midland Clock Works, Derby, who made the large memorial chiming clock in Tunstall Market Place some years ago.

MESSRS. E. P. ALLAM & Co. announce their change of address from 11 Red Lion Street, Clerkenwell Road, E.C., to 28 Gray's Inn Road, W.C., as and from January 1.

THE United Kingdom Fireproofing Company, Ltd., 47 Victoria Street, S.W., have recently secured the following contracts:—Bromley Telephone Exchange; Chester Telephone Exchange; Northern Insurance Buildings, Glasgow; St. James's Church, New Barnet; Eccles Hall, Drayton Park; new power station, Grove Road; constabulary buildings, Northallerton; new schools, Southbank; Clarence Hotel, Manchester; Ram Hotel, Doncaster; laundry block, Salford Hospital; shops and offices, Chippenham.

THE new schools, Skegness, are being supplied with Shorland's patent warm-air ventilating Manchester grates by Messrs. E. H. Shorland & Brother, of Manchester.

THE new premises of Mr. Ellis, at the corner of High Street and Market Place, Burton-on-Trent, are a noteworthy addition to the town. Mr. Fourshaw, the architect, has made the buildings quite up to date. The facings are of red Heather brick with Hollington dressings, and the chimneys are finished with "Edwardian" pots. The builder is Mr. George Hedges. The steelwork and fire-resisting floors are by Mark Fawcett & Co., of Westminster and Greenwich.

THE Colne Town Council have received the formal sanction of the Local Government Board to borrowing powers to the extent of 750*l.* for the installation of Royles's patent filtration and aerating plant at the new public baths.

"PENROSE'S PICTORIAL ANNUAL" has now reached its fourteenth volume and it gives pride of place to none of its predecessors. Messrs. A. W. Penrose, of Farringdon Road, E.C., may be said to be as successful with their "Process Year Book" as in the lifts with which their name is associated. The contents are almost bewildering in their variety, though this is inevitable in a book which is a faithful review of the graphic arts for a whole year. There are over fifty illustrated articles dealing with various kinds of process work and kindred subjects. Some of the colour prints are of great beauty, while others would admirably suit their purpose of attracting attention to trade.

MESSRS. VINCENT ROBERTS & MARR, heating and drying engineers, Leeds, have recently carried out the following contracts for heating at Roundhay Congregational Church, Belgrave Central Hall, Harehills Cemetery chapels, Alwoodley Golf Club house, new clothing factory for Messrs. Joseph Hepworth & Son, Ltd., Leeds, and numerous others, and supplied and installed a large boiler for municipal buildings, Leeds. They have fitted their patent drying machinery at the Manchester Royal Infirmary laundry, under Mr. Edwin T. Hall, V.P.R.I.B.A., and for textile work at Messrs. Pyrah & Son, Heckmondwike, and Messrs. T. Liversidge & Sons, Ltd., Huddersfield.

CORRESPONDENCE.

Earthquake-proof Houses.

SIR,—After reading of the horrible scenes and of the loss of life and suffering in Italy, and of the hundreds who would otherwise escape being buried alive in the *débris* from earthquake shock, does it not behove all thinking men, especially architects, to devise some means that will obliterate or in some way lessen the dangers? I beg to submit plans for improved housing in these stricken districts, which, if properly executed, should save the property entirely, unless the shock was sufficient to turn the house completely over. They would certainly meet many requirements both for durability and economy. It will be seen by the drawings, which are void of all intricate, elaborate and unnecessary fittings, the idea is simply to cover the whole site with cement concrete 12 inches deep, and to properly frame on the top of this foundation a framework of iron girders of a like depth, say

12 inches, crossed and recrossed, as shown, filled in with cement concrete to the top of girders and splayed on the outside, the foundation concrete to project 1 foot—not more—as in my opinion a projection of, say, 3 or 4 feet would be liable to break off under a very great shock, and therefore less foundation the better. For example, suppose an earthquake seam runs under a house thus built, is it not reasonable to believe that the combustion would glide off to the edge of the concrete, if the said foundation is sufficiently strong, before shattering the house?

Of course, the house must not be merely built on the level foundation, but should have standards attached to the iron girders and built into walls. This class of house should also be exceptionally dry, as the whole site would be made of damp-proof foundation. The framework of iron girders is shown on foundation plan, fixed in position and filled in with cement concrete, and also the proposed position for the mullions of 4 inch by 2 inch solid iron, framed and bolted together, in elevation AA and end elevation. To make these iron fittings would be very simple. The foundation girders could be made in sizes of 6 feet long, the short ones with holes cast, as shown in enlarged detail E; the long girders would be made, say, from 10 feet upwards. The 4 inch by 2 inch solid mullion ties could also be made any size, holed ready for use to fit all requirements, and could be attached to the foundation girders, as shown on detail A, B, C and D, or on any part of the foundation; also it would be very advisable to have the 4 inch by 2 inch ties built into the partition walls, say, on a level with and through the ceiling joists from front to back of house, and, of course, any quantity of these mullions and tie-pieces could be used and built into wall, as in detail D and C, in a 14-inch wall, or in practically any thickness of wall. If this is not the best way to guard against earthquakes' terrible death, I do hope and trust I have been able to offer some advice to those whose lot it is to provide plans and supervise the rebuilding of new homes for the remaining population.—Yours truly,

THOS. PERCIVALE WRAY.

Langthorpe House, Boroughbridge, Yorks.

VARIETIES.

AMONG the recent Government publications is a catalogue of wood engravings after Millais.

VARIOUS schemes, involving a total expenditure of about 60,000*l.*, are under consideration by the Matlock authorities.

MR. WILLIAM RICHARD MILLS, of 4 Constitution Hill, Ipswich, and of Dovercourt, Essex, retired builder, left estate valued at 23,976*l.* gross, with net personalty nil.

THE Local Government Board have sanctioned the borrowing of 37,000*l.* for carrying out a drainage scheme for the borough of Christchurch.

THE Board of Education have signified their approval of the plans for the new Northampton and County school, and have urged that the building should be proceeded with at once.

THE erection of a new hospital for Lewes will be commenced in a few months. The site acquired is on the Downs, and a pleasing design has been prepared by Messrs. Ernest Rüntz & Ford, of Lewes and London.

A LADY with an interest in some property in Birmingham has been fined 5*l.* and costs for attempting to give a bribe of a sovereign to an official of the Corporation's Housing Department who had warned her that she would have to appear in court.

THE extension of the South Shields Post Office buildings is under consideration by the Board of Works in London. Nearly twenty years have elapsed since the present premises were opened, and the business has very greatly increased during that period.

SOME time ago Sir Donald Currie was approached with a view to inducing him to give a donation to the fund for the erection of a new infirmary in Perth. Sir Donald replied that he was prepared to give a quarter of the cost of a new institution provided certain conditions were observed, the principal of which was that Sir Donald's own architect should be appointed. The directors of the infirmary considered Sir Donald's offer from every point of view, and reluctantly had to forego it on the ground that the time limit was too short, and that the appointment of his architect did not meet with approval.

A COTTAGE hospital is to be erected at Denbeath, N.B., at a cost of about 6,000*l*. The accommodation will include two principal wards, an emergency ward, operating-room, X-rays room, an administrative block, bathrooms, &c. Apart from the building is a mortuary and chapel. The contractors are:—Mason, John Farmer, Methil; joiners, Bruce & Sons, Dundee; slaters, J. & T. Stobie, Buckhaven; plasterer, R. Neaves, Leven; plumbers, Rolland & Co., Dunfermline; electric fittings, Oliver Melville, Kirkcaldy. The work is to be begun in the spring.

MESSRS. SPRAGUE & CO., LTD., of East Harding Street, Fetter Lane, London, forward us a copy of their pocket-book diary and letter wallet. This is one of the most valuable diaries issued, containing as it does so much information valuable to all engaged in connection with the building trade. Messrs. Sprague are the proprietors of the well known process known as ink photo, and our illustrations for the past thirty-nine to forty years give evidence of the high-class nature of this work.

THE Local Government Board have sanctioned an application of the Brampton Rural District Council, Cumberland, for an extensive scheme for supplying the parishes of Brampton, Hayton, Castle Carrock and Irthington with water. There will be between twenty-seven and twenty-eight miles of water mains and three reservoirs, which it is intended to construct of ferro-concrete. The estimated cost of the works is about 16,000*l*. The engineer of the scheme, Mr. Harry W. Taylor, A.M.I.C.E., of Messrs. Taylor, Wallin & Taylor, of Newcastle and Birmingham, has been instructed to obtain tenders for the construction of the works as soon as possible.

THE Stoke-on-Trent Town Council have received a letter from the Local Government Board relative to the application to borrow 650*l*. for a water-cooling apparatus at the electricity and destructor works. The Board are not satisfied as to the necessity for incurring that expenditure, and consider the matter should be deferred pending the settlement of the question of the federation of the Potteries towns. The Council are however of opinion that it is extremely important, both from an economical standpoint, and with a view to safeguarding the uninterrupted continuity of the electrical supply, that the proposed plant should be installed, and therefore a further application will be made to the Board, urging reconsideration of the matter.

THE Bedford Town Council have received a protest from the Carpenters' and Joiners' Union against carpenters being employed on relief works at less than the recognised rate of wages, viz. 7½*d*. per hour. The answer of the Town Council was to the effect that the carpenters were given the work in order to put a shilling or two extra per day into their pockets, and the authorities were certainly not prepared to pay 7½*d*. per hour for the kind of work they were employed in doing.

MR. EDGAR DUDLEY, on behalf of the Local Government Board, held an inquiry at the town hall, Hammersmith, on Monday, in regard to the proposal of the Great Western Railway Company to displace the occupants of a number of dwelling-houses in Providence Place, Uxbridge Road, Shepherd's Bush, for the purpose of obtaining additional access to the company's premises. It was stated that seventy-four persons would be displaced by the scheme and suitable accommodation would be provided for them.

THE laying out of Fitzalan Square, Sheffield, is to be commenced as soon as possible. The Local Government Board have given sanction to a loan for about 8,000*l*. to cover the cost. The square will be laid out in two terraces, one on the level of Market Street, and the other on the low side of the square, reached by five or six steps. Underground conveniences will be provided in the centre of the square, and an office for the tramways department will also be provided underground. When the work is complete, and the new post office and other buildings are erected, the square will be a great improvement.

AN interesting article appears in our issue this week from Mr. Challoner, who, as will be seen, is the president of the Plumbers' Institute. Mr. Challoner has had a considerable experience both in London and the provinces of the plumbing trades, and may rightly be classed as a specialist in his work. He is a Chief Examiner for the City and Guilds of London Institute, and was recently a member of the advisory committee on plumbing to the same authority. As a member of the Blackpool Town Council and the joint hospital committee for the County Palatine his experience has been of particular value in connection with sanitation generally. Although not perhaps agreeing with all our correspondent's remarks in his letter, there are points connected with it which are well worth attention.

THE Turners' Company will shortly give another exhibition of turnery—the thirty-fourth of its kind—at the Mansion House, E.C. The competitions will include turning in both hard and soft wood, the awards being for masters, journeymen and apprentices to the craft, while other prizes will be distributed among amateurs and boys in industrial and training schools. The competitions in pottery will embrace designs in terra-cotta, stoneware, earthenware, and porcelain. Beauty of design, symmetry of shape, utility, novelty, general excellence, and good copying will be rewarded. The Turners' Company have given 50*l.* towards the prize fund, in addition to promising their freedom and membership to the most successful competitors.

A BILL to authorise the Worksop Waterworks Company to construct new works and to raise additional capital has been deposited for introduction into Parliament next session. Power is sought to sink a well and erect a pumping station at Checker House, in Worksop. For the construction of these works, and for the general purposes of the company, it is desired to raise further capital to the extent of 32,000*l.* by auction or tender. The new capital is to bear interest at a maximum rate of 7 per cent. if issued as ordinary capital, and 5 per cent. if issued as preference capital. Upon this sum further borrowing powers are proposed to be exercised to the extent of 10,000*l.*

WORTHING railway station is to be reconstructed by the London Brighton and South Coast Railway Company. The present buildings on the down side will be demolished, and in their place a structure with a frontage of 250 feet will be erected. The chief provision will be a wider platform, a booking hall 60 feet long by 40 feet wide, with ticket office, telegraph office, and bookstall abutting thereon. Adjoining the booking hall will be a luggage labelling space, 30 feet by 30 feet; the general waiting room will be 30 feet by 24 feet, with a ladies' waiting room and retiring rooms adjoining. The principal refreshment room will be conveniently placed, and will exceed 30 feet in length. A new subway under the line will also be made.

THE Local Government Board having refused to sanction the proposed sale by the Hornsey Borough Council of several acres of land originally acquired for workmen's dwellings, the Council proposes to negotiate for the leasing of the land to the Improved Industrial Dwellings Company, which was prepared to purchase the freehold. The Hornsey authority has already erected houses on two sites for 308 families at a capital cost of 95,510*l.*

FROM the Local Taxation returns which were published as a Blue Book on Monday, it appears from the returns of the councils of county boroughs that there were maintained by them public roads and streets of an aggregate length, at the commencement of the year 1905-6, of 8,816 miles, and that the expenditure on the maintenance and repair of such roads and streets during the year amounted to 1,268,627*l.* This represents an average cost of 144*l.* per mile. As regards the non-county boroughs, the aggregate length, at the commencement of the year, of the main roads maintained and repaired by the councils under the provisions of sub-sections 2 and 4 of section 11 of the Local Government Act 1888, was 1,242 miles (excluding any such roads in the new boroughs), and that the expenditure on the maintenance and repair of these roads amounted to 261,643*l.*, being at the rate of 211*l.* per mile. The total length, at the commencement of the year, of roads other than main roads maintained by the councils of non-county boroughs (excluding roads in the new boroughs) was 4.612 miles. The expenditure on the maintenance and repair of these roads during the year amounted to 479,589*l.*, and represented an average cost of 104*l.* per mile. The amounts of expenditure mentioned exclude sums shown as received from accounts of the councils incurring the expenditure.

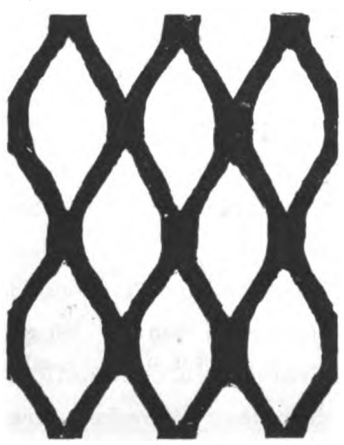
MR. JUSTICE PARKER recently gave an important decision in an action brought by the Midland Railway Company, who endeavoured to show the Derbyshire Council were responsible for keeping in repair a bridge and approaches thereof. The bridge carried the highway over the railway. The road had been to this extent diverted from its old form by the company under their statutory powers when they got leave to build their line. They had to build the bridge according to certain statutory specifications as to width and elevation, and several sections of the Railway Clauses Act provide that a railway thus bridge building shall "continue" such bridge. Mr. Justice Parker held that this duty to continue included responsibility for maintenance of the bridge and also of all its approaches, and of such fences to them and to the bridge as statute ordained the railway to construct, when the road diversion for their benefit was first made by them.

A SANITARY JUBILEE.

FROM A CORRESPONDENT.

IN January 1859 a paper was read before the Glasgow Architectural Society by Mr. John Honeyman, architect (now Dr. John Honeyman, R.S.A.), on the ventilation of sewers and soil drains, and it was accompanied by a full-size section of the trap he had invented to attain that end. Up to that time the old syphon trap, with an eye in the centre of the tongue and which usually left no water seal, had been in use. The cardinal difference in the new invention was that an eye was made at each side of the tongue, and the outfall half of the trap was sloped away with a parabolic curve instead of a circle. This not only provided the means of ventilating either section of the drain as circumstances required, but it greatly facilitated the cleansing of the trap even if a long way below the surface. This invention is now to be found throughout the world, although in few cases is its place of origin acknowledged or even known. Minor alterations (not always improvements) have been carried out from time to time, but the drain is substantially the same as was first brought under the notice of experts fifty years ago.



It is a far cry from sewer ventilation to the designing of racing yachts, yet Mr. Honeyman has acknowledged that one of the new ideas in his invention was the outcome of a close study of the illustrations of the United States schooner-yacht *America*, which in 1851 captured the famous cup in a race round the Isle of Wight. The long hollow bow and flat-cut sails were in direct opposition to the then prevailing British theory that a fast boat must have a cod's broad head and a mackerel's slender tail. The victorious challenger was a practical demonstration of the truth of the wave theory which Mr. Scott Russell had propounded earlier to a highly sceptical world. Her lines were known as wave lines, and with good reason—sharp forward and rounding in more abruptly towards the stern. This principle was the very opposite of that followed in designing English racing craft, though it was not unknown on the Firth of Forth among the Newhaven fishing boats.

It occurred to Mr. Honeyman that the curve which allowed a solid body to be most easily driven through water would, if reversed on a solid body, allow water to pass over it most easily. Consequently the longitudinal section of his trap was made on the wave-line principle.

The discovery first met the same fate which has befallen many others before and since (and which no doubt will continue to obstruct the path of improvement), viz. temporary neglect. For over ten years it was ignored by the trade. Ultimately it was taken up by a Glasgow plumber, Mr. W. Buchan, who made slight improvements with the concurrence of the inventor. But in the forty years that have since elapsed the trap has been steadily extending its sphere, and now it must be known on all the four continents. To many contractors it will be more familiar under the title of "Buchan's Trap" or "The Buchan Trap."

MR. EDWIN SEWARD, F.R.I.B.A., chairman of the Cardiff executive of the N.S.P.C.C., states that some of his friends are willing to offer a few prizes for designs or models showing how an adjustable screen of wire or other material could be readily locked to the front of a firegrate by the person quitting a room occupied by a child or children, so as to prevent the many deaths by burning.

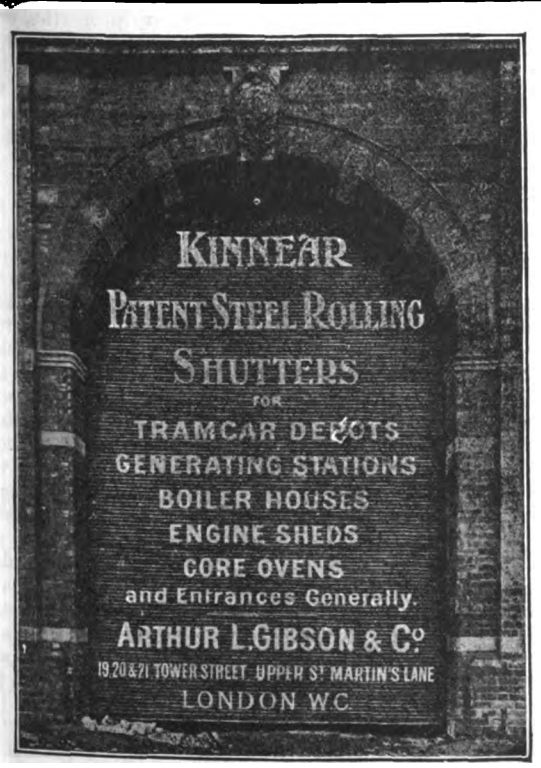
TECHNICAL EDUCATION.

By WILLIAM CHALLONER, President of the Institute of Plumbers.

IT may be of interest to take a retrospective survey of the ideals that prompted the Technical Instruction Act of 1889, and which resulted in the general establishment of technical classes for the training of craftsmen and potential directing heads of the various trades or branches which are more or less associated under the description of Building and Allied Trades. In order to fully appreciate these ideals and the conditions which dictated them, it will be necessary to consider briefly some of the pre-existing systems by which continuity of efficiency was maintained in certain trades which depended upon more or less skilled craftsmanship and knowledge of technique, as also the growth of circumstances which rendered these systems inoperative, or the decadence of the systems themselves.

By this means it may then be possible to estimate to what extent these ideals have been realised, and how far existing industrial and commercial conditions have retarded the realisation of advantages to workmen, employers and the public which higher technical training is intended to confer.



In many branches of the building and allied trades, partly owing to combinations of labour for purposes other than those of the efficient training of workmen, the old system of indentured apprenticeship had almost passed out of existence, and except in a few isolated districts and trades, remained as little more than a tradition. This left the so-called apprentice to shift for himself, it being outside the obligation of either master or man to see that he was taught his trade. It is true that in a few exceptional cases, owing to the influence of the parent or an unusually premature wisdom on the part of the boy himself, the apprentice might be found who took a special interest in his work, and devoted some of his leisure to the acquisition of knowledge necessary to supplement the ordinary training he could obtain during his hours of regular employment. The inevitable result of any such personal effort was encouragement and assistance from both his employer and the men with whom he was associated, and the youth who thus spontaneously followed such a course became eventually at least a leading man, if not a foreman, especially in those branches in which a combination of skill in craftsmanship and knowledge of fundamental scientific principles were necessary or advantageous.

Such cases, however, had become more and more the exception, and declined rapidly when and where trades unionism discounted efficiency by a standardisation of remuneration in which skill and knowledge were not considered as appreciable factors.

Although not within the scope of the present article this same influence (with perhaps one notable exception) has been responsible for an absence of the spirit of sacrifice and enthusiasm upon which the best educational facilities must depend for successful results.

The provision of convenient and cheap, if not free educational facilities, was designed to place within the reach of all the advantages which the anxious and painstaking apprentice had previously been at some considerable trouble to obtain. The result anticipated was an increase in the proportion of skilled craftsmen, if not the complete disappearance of the incompetent or "just in" workman, who either worked for lower wages, or whose discharge was already made out, ready for the time when heads were not required merely to count.

It does not appear to have been anticipated that once these classes were opened any further inducement would be necessary to secure the attendance of those for whom they were provided. In fact, in most cases the classes appear to have been intended to supplant indentured apprenticeship and shop or works' training, instead of supplementing the control which without an indenture could not secure the attendance which experience has shown will not be general if it depends upon the voluntary effort of the apprentices. It may be assumed that classes for technical instruction have been established sufficiently long to enable an estimate to be formed of how far they have contributed to the general improvement of the crafts they were designed to benefit, and also if the advantages for which they can justly claim the credit bear a proportionate value to the cost of the classes and the expenditure of time on the part of the limited number who attend them. Taking the longest technical course as five sessions it would give some four generations of workmen who have had the opportunity of participating in such advantages as are conferred by these classes; and although, for reasons which may be considered later, the

number of those availing themselves of the privilege has been but a small proportion, there have been sufficient to test the value of the classes in attaining at least the direction which would ultimately lead to the ideal which prompted their establishment. It cannot by any stretch of optimism be claimed that the improvement generally, or in any branch, shows an adequate return for the outlay in time or money. Workmen who "think" are not proportionately more numerous than before these facilities for technical training were placed within easy reach.

To appreciate the reasons for this whole or partial failure it is necessary to consider briefly some of the conditions, or rather omissions, in connection with the several factors upon which the anticipated results of this educational movement depended.

For many of the earliest students who attended the first courses at the newly established technical schools novelty was the enticement. But owing to the absence of connection between what little had survived of the knowledge received at the elementary schools and the higher technical subjects with their application, the task proved too great a mental effort, and this class of student became rapidly a decreasing quantity and had disappeared entirely when the time for examination arrived.

It is true there were in every district a few enthusiasts who had been waiting for the opportunity thus offered, but their number was inconsiderable, and for reasons to be submitted later they did not directly influence the general efficiency of the trades they represented.

(To be continued.)

NEWPORT BRIDGE.

IN consequence of a general feeling of uneasiness as to the stability of Newport Bridge in Monmouthshire, the Corporation recently instructed Mr. R. H. Haynes, M.I.C.E., the borough engineer, to prepare a report on the subject.

Newport Bridge, built in 1800, was widened in 1865-6; while in 1892, upon the bridge passing under the control of the County Borough (formerly it had been a county bridge) it was widened and the western approach raised. The bridge has a total length of 475 feet, and a width from face to face of the arches and spandril walls of 24 feet 3 inches. It has five arches and four inner piers. Three different classes of stone are found in the structure.

Considerable differences of opinion exist as to the necessity for widening in order to provide for the existing traffic, not a few expressing the view that except on special occasions the bridge is sufficient for the normal movement. Mr. Haynes expresses no opinion on that point. Assuming that improved cross-river communication is necessary two main questions present themselves—(1) the best means of widening Newport Bridge if on investigation widening be found practicable and economical; (2) the erection of a new bridge should widening prove too difficult or costly.

Recently trial holes have been sunk on the western side of the piers, and borings have been made on the southern side of the piers. No apprehension need at present be felt with regard to the strength of the footways. So long as the bolts remain in good order the footways will be stable. During the work of renewing the footpaths in 1892 the spandril walls showed signs of movement. Recent measurements indicate that this movement has appreciably increased in the interval. The western abutment wing walls are plumb on both sides. The eastern abutment north wing overhangs a maximum dimension of four inches in a height of 18 feet, but has not recently shown signs of movement. One of the arches is cracked in four places in the eastern haunch and water sweeps through a haunch in another arch.

According to text-books rubble masonry should not be loaded to a greater extent than four tons per square foot. Portions on the arches of Newport Bridge are now carrying more than three and a half times that load. During the passage of a heavy road locomotive, hauling a train of wagons, the vibration in the structure was surprising. Vibration especially when progressive is a notable cause of deterioration in masonry structures, and must eventually result in extensive mischief, not the less dangerous because it is unseen. There are various reasons for regarding the arches with distrust. The overloading of the structure is the more serious because investigations have shown that the foundations of the piers are unsatisfactory. Three of the piers rest upon sand and silt, and careful research for piles was made without effect.

Mr. Haynes discusses the possibilities of reinforced concrete bridges, points out their advantages and difficulties, and leaves it to the Corporation to come to a decision. He discusses the possibility of widening or otherwise patching up the old bridge, but points out that it is economically unsound, and therefore turns to the question of the most suitable type of bridge. Three principal factors are considered—capital cost, low maintenance charges, and durability. A stone bridge best filled the two latter conditions, as its maintenance costs practically nothing. A steel bridge is less expensive in first cost, but its maintenance is a considerable item when capitalised, and its life probably shorter than that of any other. During recent years reinforced or armoured concrete has been extensively adopted for bridge structures of all kinds and possessed great merits. In the present instance a steel bridge has peculiar disadvantages; and the general strain of the report points to armoured concrete as the most suitable material.

Mr. Haynes puts forward alternative schemes for a stone or armoured concrete bridge to replace the present structure, and for a new armoured concrete bridge about 80 feet north of the present one. This would be 50 feet wide between the parapets. It would be level from the western abutment to the eastern pier, when it would fall a gradient of 1 in 25 to the eastern approach road, which would have a similar gradient. This road would curve southward and form a junction with Clarence Place immediately opposite the site of the Technical Institute. The opening at the point of junction would have a width of 120 feet between the kerbs. The western approach would have a slight rising gradient 1 in 296 from Shaftesbury Street. The junction with that street would be formed by curves extending northward and southward, giving a width of nearly 90 feet between the kerbs at the point of junction. The curve to the southward would cut through the Shaftesbury Hotel, and so arrange as to effect a widening of Shaftesbury Street opposite the Castle Hotel. The western approach would pass through the southern and central towers of the Castle, joining up to the bridge at the Castle walls. The purchase of land and properties would be a serious item in the total cost. The proposal was a perfectly practical one, though it was but fair to point out that apart from its costliness it had certain physical disadvantages. The original suggestion to place the bridge and western approach between the northern and central towers of the Castle had been abandoned owing to serious disadvantages which it presented on detailed investigation of its possibilities. The cost of this scheme, including the purchase of all the necessary properties, trade compensation, and works, but excluding any legal or engineering costs, was estimated at 79,000*l*. If a stone bridge was substituted for a concrete bridge the cost was estimated at 116,000*l*. A concrete bridge could be erected in fifteen months, a stone bridge in two and a half or three years.

Mr. Haynes also submits a plan for the removal of the existing bridge and the substitution of a new bridge 50 feet wide between the parapets. This scheme would include the erection of a temporary bridge to the northward of the present structure. This temporary bridge would be approached on the western side of the Castle site between the southern and central towers, from the eastern side by a temporary roadway through the site now occupied by workshop building. The temporary bridge would be 30 feet wide and would be constructed on timber tressels and side spans, with a steel central span of a width suitable for the steamboat traffic to and from the Crindau gasworks. The new bridge would have a roadway of 32 feet 6 inches wide, with two lines of tramway laid in the central position, giving a statutory clearance between rails and kerb. The footpaths would be 8 feet 9 inches wide. The estimated cost of the scheme, including a stone bridge, temporary timber bridge, temporary and permanent rearrangement of mains and tramways, road and footway works, purchase of properties at the eastern end but excluding the purchase of any land on the Castle site or engineering or legal expenses, was 91,000*l*. If an armoured concrete bridge be substituted for the stone bridge, all other items remaining the same, the estimated cost is 56,000*l*.

Mr. Haynes concluded that a new bridge on the site of the existing one would be less expensive in the first cost and would possess additional certain merits. Disturbance of properties would be reduced to a minimum, no part of the Castle site would be permanently appropriated, and except during reconstruction there would be no deviation of the main traffic artery. The balance of advantage was altogether in its favour, and it was recommended as the proper solution of the problem. He hesitated to express a very decided view with regard to the continued stability of

the existing bridge, but bearing in mind that it was built to accommodate what might not unfairly be described as village traffic, that it is now carrying the traffic of a great community for which it was never intended, as well as other matters of design and structural fitness, it must be said that its construction cannot be indefinitely postponed and should not be delayed.

FALMOUTH Corporation have under consideration an application for permission to establish a system of electric railless traction. Schemes have been carried out in other places, particularly on the Continent, with successful results. The object of the railless system is to run in towns where the traffic is manifestly insufficient to support an ordinary electric tramway, and the system is especially designed for places where the streets are too narrow to permit of rails being laid because of the interference with ordinary traffic. The control arm allows the cars to deviate 10 or 12 feet on either side, and to steer in and out of the traffic and follow the convolutions of roads and streets. It is hoped to be able to secure the current required from the Falmouth Electric Light Works. If permission is obtained to run the cars through the main streets a definite scheme will be prepared with estimates of cost of construction and equipment, and an effort will be made by the parent company to form a local company to finance the scheme.

THE Tees Conservancy Commissioners at Middlesbrough have received inquiries during the year with respect to the purchase of reclaimed land, principally on the north bank of the river Tees, for the erection of large manufactories and other works. One existing disadvantage is the want of road and railway communication between Grantham Creek and Seaton Snook, but this is about to be met by the North-Eastern Railway Company, who had undertaken to construct the roads and railways required. With regard to the reclamation of land on the south side of the river arrangements are being made which would enable deep-water wharves, ironworks, manufactories, &c., to be constructed between Eston Jetty and the Redcar Wharf, close to the navigable waterway similar to those now existing at Middlesbrough.

MOTORS AND ROADS.

A CONFERENCE was held recently in Glasgow between the Scottish Automobile Club and the road surveyors of Scotland.

Mr. Robert Drummond, road surveyor for the County Council of Renfrewshire, read a paper on "The Work of the International Road Congress in Paris last October, and the findings come to as bearing on the road practice in this country." Before dealing with his subject proper, Mr. Drummond, by way of connecting the past with the present, made reference to the unsatisfactory condition of many of our highways in this country between the abolition of the old toll system and the passing of the Local Government Act of 1890, in the course of which he pointed out the improvements effected through the introduction of the steam roller. There were now 250 steam rollers, with forty or fifty motor tractors, employed by the County Councils of Scotland, as well as a large number of boring and breaking machines, the probable cost of which was 200,000*l*. He next dealt with the changes which had taken place on our road systems as following the advent of the motor and the other self-propelled modern vehicles, and said that at the recent Congress there was considerable discussion over the questions of speed and weight of motor-cars and mechanical transports. The Congress made a sharp distinction between town roads and rural roads, and it was universally acknowledged that macadam was as yet the best known and the most suitable material for roads in country districts. The raising of dust by quick-going machines and the forming of separate roadways were also considered. With regard to the dust nuisance it was urged that tarring was undoubtedly an efficient remedy, and one roadway, with a width of six metres, or 19 feet 6 inches at least, was, proportioned to the intensity of traffic, recommended, saving in exceptional cases of broad pleasure avenues of which several roadways might be formed. The effects of the means of locomotion was one of the outstanding questions at the Congress. There was no doubt that the running of fast motor-cars with pneumatic tyres caused the disintegration and uplifting of the smaller particles of road materials. The greater the speed the more this condition was accentuated. Too sudden an increase in

speed, as well as too sharp an application of the brakes, considerably increased the damage to the surface, while all changes of speed also did harm, but in less degree. In taking the curves, the action of the centrifugal force was added to the ordinary effects of speed and considerably increased the damage. It was important to reduce that damage as much as possible, and that could be done by using pneumatic tyres or shoes or covers exclusively of pliable materials, which simply meant that the tyres of the wheels of heavy motor-cars or traction engines should be smooth. It was admitted that the running of heavy motor-cars had a tendency to damage the road principally by causing depression and ruts, and to avoid this it was important that the pressure per running inch should be moderate in relation to the resistance of the road to shear. All automobile vehicles employed for public conveyance might be advantageously used without injuring the road to any appreciable extent if kept at a reasonable weight and within a reasonable speed, and a formula was suggested and embodied in the conclusions of the Congress reducing the weight at present allowed by one-fifth. There was great diversity of opinion over this question, not a few remarking that many of the heavy motor-cars to be seen on the roads were much too heavy, and that in point of fact they were little else than traction engines in disguise. In this connection it was found to be difficult, in the present condition of the roads and of the automobile industry, to arrive at a satisfactory solution of the difficulties arising from the traffic of motors. But in order to affirm the data and make them more complete, the Congress considered it desirable to collect exact particulars controlled by competent authorities, so as to determine the relations to be kept between the constitution of the roadways, the power of resistance of structures connected therewith, and the speed, right width of rims, diameter and nature of the tyres of the vehicles, the method of suspension, the number of axles, and their distance apart. The conclusions arrived at by the Congress, however, clearly showed that the modern traffic problem was a very serious one. With regard to damage caused by weight, the general opinion was expressed that some alteration was required in the size of the wheels on heavy motors. There was a lack of due proportion between diameter of wheel, breadth of tyre, and load carried. As small wheels if heavily loaded had the tendency to push or move stones out of their places they were most destructive to road surfaces, and no additional breadth of tyre would compensate for want of diameter. He was of opinion that however well the surface of a macadamised road might be formed, nothing short of an "armour"-proof road would suffice to resist the action of heavily-loaded motors; but in this matter motor-car manufacturers could greatly assist by altering their designs, and thereby show some regard for existing public roads. The Scottish road surveyors certainly recognised that it was their duty to construct and maintain the public highways in a condition fit to carry all traffic legalised to pass over them, and a great advance generally, and particularly towards coping with the new means of locomotion, had undoubtedly already been attained, whilst the results of recent experiments would also encourage local authorities to surface all roads in or around urban areas, villages, and popular places with material such as tar macadam or tar spray for the abatement of the dust nuisance. Regarding the roads in the country, they were gradually being improved by using the best material both in metal and hard binding, widening metal beds by filling up deep side channels, and obtaining a good side resistant, as well as reducing the camber to make it suitable to the requirements of all traffic. The standard of road maintenance in the interests of the public had altogether been very much raised since the inception of the County Council.

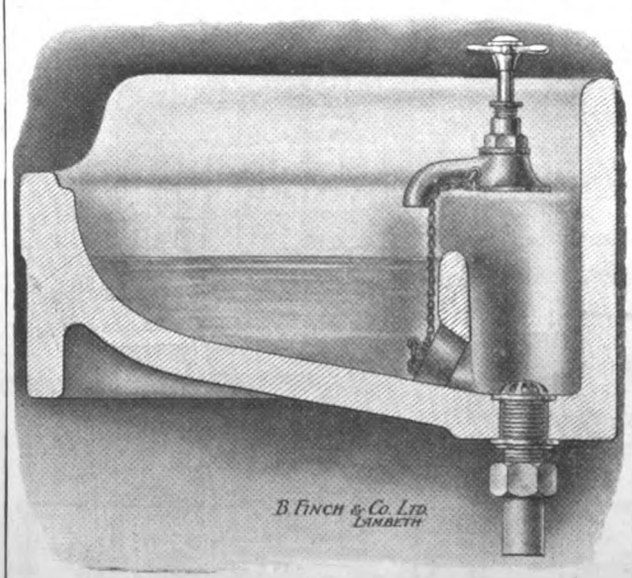
In Renfrewshire, in 1890-1, 23,505*l.* was spent on the highways, and in 1907-8, 35,710*l.*, showing an increase of annual expenditure of 12,215*l.*; whilst Lanarkshire in the same two periods spent 53,710*l.* and 89,805*l.* respectively, or an annual increase of 36,098*l.* Taking the whole expenditure over Scotland for the same periods, there was an annual increase of over 50 per cent.

The question might very well be asked, however, how was any further serious expenditure to be met without creating undue burdens upon the local ratepayers? Officially it was not customary, Mr. Drummond continued, for surveyors to discuss or suggest where money was to come from, their duties being confined to advising what sums were required, and after obtaining the sums requisitioned to spend them to the best advantage; but as they were there

C. JEAKES & Co., ENGINEERS, 51, Gt. Russell St., LONDON

COOKING, LAUNDRY, HEATING, VENTILATION, Etc.

Digitized by Google



to discuss matters non-officially the question of finance might be touched upon, for after all was said any drastic change in the methods of road maintenance meant increased expenditure. Now he considered that all roads in urban and populous places might be surfaced with materials treated with tar in some form without unduly increasing the expenditure, and the results of experiments showed that road surfaces treated with tar tended to economy in many ways, and gave added comfort to the inhabitants. But no matter what steps might be taken by local authorities towards strengthening and improving our roads, their surveyors would have to advise them that unless some moderation was effected both in the speed and the weight of motor traffic, nothing short of a bituminous binding would serve to keep in good order a macadamised surface, however good the materials used in it, and however well it might be kept. It was nothing unusual nowadays for a new coating of metal to be applied on our main lines, rolled hard, and finished to a proper contour with altogether an excellent surface, but in three months' time the surface would be tracked and pitted with "pot" holes at irregular intervals by motors, and it was nigh impossible to repair the damage without scarifying and re-rolling. Any attempt to repair those pot holes with patching metal was rendered abortive in view of the fact that the first fast car that came along and was carelessly driven would undo in a few minutes the whole day's work of the surfaceman and scatter the material in all directions. It was the settled opinion of all surveyors that motorists could help matters very much with a little care, and with some consideration for the road. Many stretches of the main roads had been surfaced under the expectation that motorists would be induced to shift their line from the centre, but no good results had been attained. Taking into consideration the condition to which the roads had been brought, and which might be said to meet all reasonable requirements, he thought that inconsiderate driving was largely responsible for the damage caused. By inconsiderate driving he meant excessive speed and adhering to one track. Beyond this, of course, there was the question of weight and steel-studded tyres. There was another side to inconsiderate driving, a side, too, which was not generally remembered by motorists—that it was as easy to bespatter other users of the road with mud in wet weather as to becloud them with dust in dry weather, even although they might be on the footpath. In concluding, Mr. Drummond remarked that he thought he had said enough as a contribution towards the evening's discussion, and he would only hope that a solution of this question satisfactory to the users of the road would be reached in the near future, although he rather doubted it might not be quite so satisfactory to them as ratepayers.

THE West Bromwich borough surveyor has submitted plans and estimates for fencing, levelling, and laying a drain through the land at Bromford Lane, for the purposes of allotments. The estimated cost is 1,200*l*., and the committee recommend that the work be carried out, and application be made to the Local Government Board for sanction to borrow the money.

MR. C. F. WIKE, city surveyor, Sheffield, in his annual report, states that the number of houses erected and certified for occupation during 1907 was 1,753, and as compared with the number (1,904) certified during the previous year shows a decrease of 151 houses, or 7.9 per cent. This is a less number than have been erected in any year since 1897, when the boom in the building trade first made itself felt. These figures bring up the total number of houses erected in the city under the Sheffield by-laws since the year 1864 to 50,647. Other buildings have been completed during the year to the number of 358, an increase of sixteen on the number (342) completed in the previous year. There are nearly 400 miles of streets in Sheffield. Nearly twelve miles of new roads were added during the last year. Of the 400 miles, 299 are "adopted" and 97 unadopted. New sewers 10½ miles long were constructed last year. There are still 44 miles of rubble sewers needing reconstruction. Last year 5½ miles were dealt with. The average number of workmen in the highway department last year was 1,812. The highest number employed during the year was 2,209. Workmen's wages totalled 106,715*l*., an average of 1*l*. 2*s*. 8*d*. per man per week.

Melbourne, Sydney, Brisbane, and Perth, Australia; Wellington, Christchurch, and Auckland, New Zealand; Launceston and Hobart, Tasmania.

SOUTH AFRICA—*Central News Agency, Ltd.*

Telephone No. 4725 Holborn.

NOTICE TO ADVERTISERS.

Under no circumstances whatever can the Proprietors of this Journal guarantee alteration of copy if received after the first post on Tuesday mornings, and no proofs can be submitted if copy arrives later than first post on Saturday mornings.

EDITORIAL NOTICES.

In view of the many difficulties which are certain to arise in connection with the law, practice rules and procedure under the Workmen's Compensation Act, we have added to our staff A VERY EMINENT BARRISTER, who has made the subject a special study, and will be glad to answer in the columns of this paper any questions relating to the complicated matters arising from the provisions of this difficult Act. Our LEGAL ADVISER will further answer any legal question that may be of interest to our readers. All letters must be addressed "LEGAL ADVISER," Office of "The Architect," Imperial Buildings, Ludgate Circus, London, E.C.

The Editor will be glad to receive from Architects in London and the Provinces results of Competitions and Tenders and other particulars of Works in progress in which they may be interested.

No communication can be inserted unless authenticated by the name and address of the writer—not in every case for publication, but as a guarantee of good faith.

Correspondents are requested to make their communications as brief as possible. The space we can devote to Correspondence will not usually permit our inserting lengthy communications.

The authors of signed articles and papers read in public must necessarily be held responsible for their contents.

TENDERS, ETC.

*** *As great disappointment is frequently expressed at the non-appearance of Contracts Open, Tenders, &c., it is particularly requested that information of this description be forwarded to the Office, Imperial Buildings, Ludgate Circus, London, E.C., not later than* 2 P.M. *on Thursdays.*

COMPETITIONS OPEN.

LYNTON (DEVON).—Jan. 30, 1909.—Sketch plans to scale and sketch designs, with approximate cost for Wesleyan church and additional buildings, on land near the town hall. THE issue of *Country Life* for January 9 contains an interesting illustrated article on The Moot, Downton, Wiltshire, the residence of Mr. E. Pitts Squarey.

THE Shoreditch Borough Council have instructed their standing committees to give preference, when accepting tenders or placing orders, to goods of British manufacturers.

THE Borough Council of Hammersmith are contemplating the expenditure of over 19,000*l.* on extension of generating plant, &c.

A NEW parade at the sea front at Bexhill is to be laid out. A prominent feature will be the covered colonnade, semi-circular in shape and with an open-air bandstand which will accommodate 1,200 people. About 13,000*l.* is the estimated cost.

A BILL has been deposited for introduction into Parliament next session under which it is proposed to incorporate a company under the name of the Donington Water Company. The capital is to be 12,000*l.*, with powers to raise by debenture stock a further sum of 4,000*l.* The water is to be obtained by sinking a well and erecting a pumping station and water tower in Donington.

TRADE NOTES.

MESSRS. PECKETT & SONS have placed in the centre of their calendar a coloured picture of one of their locomotives having cylinders 18 inches by 24 inches. At their Atlas Works in Bristol they have in stock locomotives of various sizes and gauges. Their speciality is tank locomotives.

MESSRS. OGILVY & PARTRIDGE, general brassfounders, of Birmingham, inform us that they have acquired large and extensive factories, known as the Camden Works, Browning Street, Birmingham, where their business will be carried on in future.

THE Sussex Portland Cement Company, Ltd., have every right to adorn their calendar with an excellent pen-and-ink sketch of Winchester Cathedral by Mr. A. Freeman, for their "Newhaven" brand is being exclusively used throughout the important restoration works at that historic structure. A significant fact is that the same cement is being employed on the "Auld Brig o' Ayr."

EVEN in their calendar William Morris & Co., Ltd., Ruskin House, S.W., have been able to introduce an element of beauty and pleasing design, whether in the brown paper, the black printing, or the red seal. An excellent idea is the sliding indicator which frames the current day of the month. It is self-supporting, and would not be out of harmony on any writing table, and it may be attached to a wall. If any criticism might be offered, it is that there seems to be some difficulty in extracting the monthly tablets. This could be very easily remedied.

THE Ratner Safe Company, Ltd., received last month two exceptional orders. The first order is for a safe deposit to be erected in Bombay of the very best construction, of a minimum thickness of 1½ inch solid drill-proof steel, fitted with four rooms to hold nearly 4,000 safes, and numerous strong rooms. The other order (amounting to nearly 5,000*l.*) is for strong-room fittings for new Government buildings at Pretoria. The order was won in competition against English and American makers.

THE well-known preserving and disinfecting properties of copper play an important part in the satisfactory results obtained from the use of Barol on all kinds of timber. Barol is manufactured by a special process, in which certain copper compounds are mixed with oils which themselves have great powers for the preservation of wood. It is applied like paint with a brush, and the covering capacity of a gallon is about 350 square feet of dressed lumber and 250 square feet of rough lumber for the first coat. Barol has a wide range of usefulness, for it is efficacious for every variety of use to which timber may be put, whether in boats, piles, posts, fencing, telegraph poles, railway ties and so on. It protects against dry rot, decay and other evils to which wood is heir. In colour it is ornamental, for the tint of the preservative is a pleasant brown and the wood does not require painting. This is an important recommendation for its employment in buildings. The following simple test is suggested by the manufacturers:—Fill a small bottle about half-full with Barol, add a few drops of muriatic acid and shake this mixture. File or rub a nail with sandpaper till it is perfectly clean and put it in the mixture. After eleven or twelve hours take the nail out, and if the genuine Barol has been used the nail will be covered with copper. The principal representative of the manufacturers in Great Britain is F. S. Schröder, Mincing Lane House, E.C., who has appointed local agents.

THE latest scheme of the London and Lancashire Fire Insurance Company is to issue policies covering consequential loss following fire, payment of standing charges and increase in cost of working afterwards due to partial or total stoppage of work. It may be mentioned that this company (which offers security amounting to nearly four and a half million sterling) so arranges these insurances that (1) there is no necessity for the proposer to declare his net profit, because the policy is taken out to cover both net profit and standing charges in one sum; and (2) in the event of loss, the insured's books are not examined by any official of the company, but only by the confidential accountant mutually appointed by the insured and the company for the purpose of ascertaining the amount of loss.

THE Royal Institute of British Architects will hold a special general meeting, convened by the Council under By-law 60, on Monday, the 25th inst., at 8 P.M., to read a paper on Part V. of the London County Council (General Powers) Bill, dealing with the Amendment of the London Building Acts, by William Dunn.

Scagliola Marble

An old Italian process, revived in the early part of the Sixteenth Century by Guido Sassi; is not a surface decoration, but a thoroughly artistic material. It was largely used by the Florentines in some of their most elaborate works, and was introduced into this country by Mr. J. Wyatt about 1750. It has been manufactured by this firm for the last 85 years, and fixed in many of the most important buildings in the Kingdom.

BY SPECIAL APPOINTMENT

TO HIS MAJESTY.

SPECIALITÉ for surrounding Iron or Brick Cores.

These being fixed in the ordinary course of construction the SCAGLIOLA can afterwards be fixed round WITHOUT SHOWING JOINT.

Prize Medals, 1851 & 1862.

ILLUSTRATIONS.

HOLBORN TOWN HALL.—ADDITIONS—THE PRINCIPAL ENTRANCE—THE COUNCIL CHAMBER.

BARRY, NORTHWOOD.—ENTRANCE VIEW—GARDEN VIEW.

LIVING ARCHITECTS.—NO. 2, MR. T. G. JACKSON, R.A.

VARIETIES.

THE Morecambe Town Council has decided to spend 6,250*l.* on improvement of the sea front.

MESSRS. HATCHARD, SMITH & SON, architects and surveyors, have removed to 76 Watling Street from Finsbury Pavement, E.C.

A NEW joiners' shop is to be erected in Portsmouth Dockyard, on the site of the block wooden stores facing the official residences, at a cost of 20,000*l.* Only 5,000*l.* has been provided for the work in the current estimates.

THE Darfield Urban Council have decided to apply to the Local Government Board for sanction to borrow 6,500*l.* for the new sewage works scheme. This amount includes 350*l.* for a sewage works manager's house.

THE Local Government Board has given its sanction to the Eccles Corporation proceeding with the erection of twelve artisans' dwellings in Corporation Road, under the Eccles Housing Order, 1901.

THE Victorian Railway Commissioners have advised against the proposed electrification of the railways in the neighbourhood of Melbourne—a scheme which was recently referred to in these columns. Their report is directed against the general proposal to electrify the railways.

A SUB-COMMITTEE of the plans and works committee of Edinburgh Town Council recommend an extension of the accommodation for washing at Simon Square public washhouses from forty to sixty stalls, at an estimated cost of 640*l.*

THE Falmouth Town Council have approved the plan and estimate of the surveyor for dealing with the surface water in the area draining to Market Strand. Application will be made to the Local Government Board for sanction to borrow 547*l.* for the work.

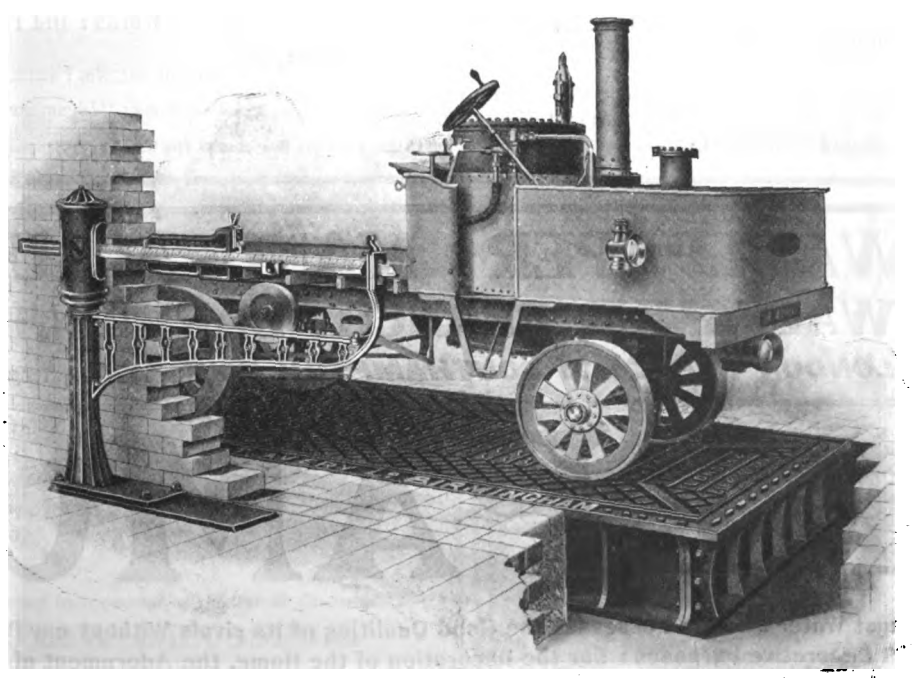
THE Royal Commission on Coast Erosion and Afforestation, presided over by the Hon. Ivor Guest, M.P., have been considering within the past few days their interim report on that branch of their inquiry which relates to afforestation, and it will probably be issued to the public about the middle of the month.

MESSRS. P. WALKER & SONS, LTD., of Burton and Warrington, have decided on the erection of a new brewery at Burton on the present site at Shobnall for brewing Lager beer. The whole of the plant has been ordered, and the necessary alterations will be put in hand forthwith.

MR. COTTERELL at the last meeting of the Bath Town Council moved the adoption of the report of the special committee which was appointed to consider the desirability of augmenting the attractions of the city with a view to making it still more popular to visitors.

MR. W. N. BLAIR, C.E., borough engineer and surveyor of St. Pancras, has been elected president of the Incorporated Association of Municipal and County Engineers, who will hold their annual meeting in London from January 24 to January 26.

BUCKIE Town Council have decided to accept the 33,000*l.* Government grant arranged by a provisional order to extend the harbour. The weakest portion of the present structure would be demolished for the extension, and the proposal is to borrow for both purchase and extension over fifty years, thereby effecting a saving of 400*l.* yearly.



MR. J. G. NEWBIGGING, chief engineer of the Manchester Corporation's gas department, has been unable to accept an invitation from the Calcutta Corporation to visit India and advise them as to the lighting of their city. Mr. Newbigging is found to be indispensable in the important work on hand in Manchester.

IT is proposed to construct docks at St. Just Point, Falmouth, inside the harbour, capable of accommodating the largest ships afloat, and also of dealing with the very extensive china clay and fish traffics. The scheme includes a railway connecting the docks with the Great Western main line and the Cornish china clay district in the northern part of Mid-Cornwall, whence are exported annually about 750,000 tons of china clay. The cost of the scheme is estimated at nearly 800,000*l.*

THE Ecclesiastical Commissioners on the recommendation of the Bishop of London have allocated 10,000*l.* for the erection of a church in place of the temporary building of St. Peter's, Colney Hatch Lane, Muswell Hill. The plans are being prepared by Messrs. Caröe & Passmore, architects to the Commissioners, and building operations will be started in March.

PRINCESS ALEXIS DOLGOROUKI is building a new house at Taplow, which she hopes to occupy next summer. The place is not far from Taplow Court, Lord Desborough's seat, and when completed, says the *Estates Gazette*, will be one of the pleasantest and most perfect houses up the river. Princess Alexis Dolgorouki has been her own architect, and the residence has been built entirely after her own designs.

THE Nottingham Corporation have agreed to construct a new outfall sewer for Sherwood which (inclusive of the reconstruction of sewers in old streets) will involve an outlay of 21,000*l.* The total acreage to be drained by the sewer is 546 acres, much of which is still unbuilt upon. The total length of the outfall sewer will be 2,550 yards, and that of the smaller sewers at Sherwood 2,300 yards.

THE Hertfordshire county education committee recommend to the County Council that an offer be made to the governors of the Watford Grammar School of 9,000*l.* for their buildings in Derby Road, and that 1,000*l.* be spent in converting the buildings into a higher elementary school. It is further proposed to make a grant of 7,250*l.* towards the erection of a grammar school on the Cassiobury Park estate.

THE Accrington Corporation distress committee report that of those unemployed for whom work was found by the Corporation thirty-four have been discharged for laziness and not earning their pay, sixty-nine have left, twenty-six have returned to their former employment, or have found other work, and two have died. One of the latter had been off a few days drinking, and died when returning to his work. The other died after having done one day's work.

THE Manchester Corporation are bound by agreement to supply electric current for lighting and power purposes in the urban district of Droylsden. A considerable outlay on cables will be entailed, and before proceeding with the work the Corporation are desirous of ascertaining the number of probable users. The District Council maintain that under any circumstances the city authority must carry out its obligations, and the general purposes committee has decided to make representations to that effect to the Corporation.

DURING the summer a number of tests have been made in mines and quarries with a new explosive known as "Mitchellite," and the announcement is now made that a company is to be formed for the manufacture of this explosive. Already a site for the factory, extending to thirty acres, has been secured on the farm of Clay Knowes, near Bonnybridge and Greenhill Junction. Machinery will be installed capable of manufacturing 20,000 lb. per day.

THE Mayor of Paddington has stated at the Borough Council, in regard to the refusal of the London County Council to sanction a loan of 10,000*l.* for paving works which it was decided to undertake now in the interests of local unemployed workmen, that a communication had been received from the President of the Local Government Board intimating that he would be disposed to consider favourably any appeal made to him against the decision of the County Council.

THE Whitley Bay and Monkseaton Urban District Council recently instituted a competition for a public shelter to seat 1,000 persons, and promenade for 400, to cost 1,200*l.*, a premium of 20*l.* being offered for the best design. Over thirty designs were received, many of which could not be carried out for the amount stipulated. The design submitted by Mr. Edward Cratney, of Wallsend and Sunderland, has been selected by the Council, and the above premium awarded to him.

THE London County Council, replying to the Stepney Borough Council, which passed a resolution urging the employment of labour in productive works in order to relieve the unemployed, state that they have decided to ask Parliament for authority to construct, at an estimated cost of 75,000*l.*, a bridge over the Waterworks river at Quartermile Lane and an approach to the bridge from New Temple Mills across Hackney Marsh.

A LOCAL GOVERNMENT BOARD inquiry was recently held at Watford into the application of the Urban Council to borrow 16,500*l.* to purchase 50 acres of the Cassiobury Estate for a people's park. The Local Government Board have now

written stating that they consider the price charged too high, as the vendor's profit would be 60*l*. per acre. The Urban Council have appointed a deputation to interview the Board.

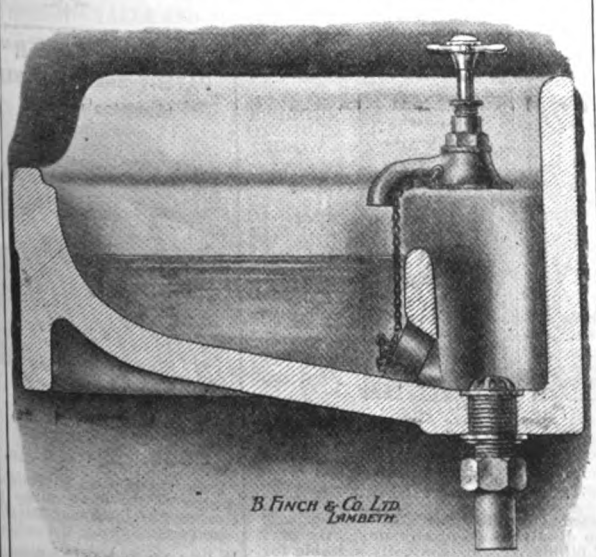
THE Greenock Dean of Guild Court have granted warrant to the trustees of the arch-diocese of Glasgow for the erection of a combined elementary and higher grade Roman Catholic school, four storeys in height, at the corner of Patrick and Houston Streets. The new school, which will accommodate 1,000 children, is to cost about 10,000*l*. The work of building will begin at the end of next month, and is expected to occupy about nine months. Mr. Walter R. Watson, Glasgow, is the architect.

THE committee of Colwyn Bay National Eisteddfod have opened negotiations with the Manchester Syndicate which has acquired land in Colwyn Bay for the purpose of erecting, at a cost of 40,000*l*. a large pavilion, which will include skating rink, billiard hall, &c., with the view of securing the use of the skating rink, which will seat 6,000 people, for the purposes of the Eisteddfod. The committee tentatively have offered the syndicate a rent of 1,000*l*. for the use of the rink during the Eisteddfod week.

FOR the position of borough engineer and surveyor of Middlesbrough 129 applications have been received. The streets committee have reduced the number to the following nine:—Mr. Leslie Roseveane, chief assistant engineer and surveyor of Birmingham; Mr. Frederick Beaumont, deputy borough engineer, Wolverhampton; Mr. Nelson F. Dennis, West Hartlepool; Mr. A. T. Gooseman, Bootle; Mr. Thomas W. Joyce, Dartmouth; Mr. Frank Latham, Penzance; Mr. H. B. Bongley, Manchester; Mr. Edmund S. Pinkerton, Belfast; and Mr. S. E. Burgess, South Shields. Mr. S. E. Burgess was appointed on Wednesday.

THE Colne Town Council have agreed that in cases where private street works are carried out by the owners of property in pursuance of notices served under Section 150 of the Public Health Act, 1875, and the Corporation are requested to superintend the execution of the work, a commission of 2 per cent. on the cost be charged to the respective owners, this sum to be in lieu of the 5 per cent. commission which the Corporation are entitled to charge in cases where the whole of the work is carried out by them out of money borrowed for the purpose in pursuance of sanctions to loans granted by the Local Government Board. This resolution will apply to all private streets, whether front or back streets.

A BILL has been deposited for introduction into Parliament next session under which power is sought to incorporate a statutory company under the name of "The Brighton Casino and Marine Palace Company." It is proposed to erect a pier beginning in the esplanade nearly opposite West Street and extending over the foreshore and into the sea for a distance of about 8 chains. At the termination of the pier it is proposed to erect "a marine palace, pavilion, casino and winter garden with assembly, concert, refreshment and other rooms." The capital to be raised for these purposes is 250,000*l*.



IN 1908 the Local Government Board sanctioned 4,630 loans, amounting to 11,664,212*l*., for purposes other than those of the Poor Law Guardians. Compared with 1907 this is an increase of 2,303,423*l*. Already this year eighty-two loans, for 187,920*l*., have been approved. Between August 1 last and January 1 475 applications were made for the sanctioning of loans for works by which employment would be afforded to the unemployed. The amount involved was 2,325,247*l*. In the corresponding period of 1907 the number of applications was sixty-eight, and the total involved was 223,602*l*.

THE village institute at Robertsbridge, Sussex, which was designed by Mr. George Hornblower, F.R.I.B.A., of London, was opened by Lord Brassey on January 6. The building comprises a large hall, arranged for theatrical performances and capable of seating 200 persons comfortably; a large billiard room, games room, library, &c. The building conforms with the style of the bulk of the houses in Robertsbridge, and the roof is covered with hand-made local tiles. Mr. Samuel Harvey, of Rye, was the builder, and Mr. James Gray, of Chelsea, provided the heating installation.

DR. REGINALD FARRAR has issued to the Local Government Board his report on the sanitary and administrative affairs of the Whitby rural district, dealing especially with those portions of the district resorted to by summer visitors. He considers that on the whole the cottage property in the rural district is in a fair structural condition. The con-

struction of villa residences in the villages described as places of resort for visitors illustrated, however, in numerous instances the urgent need of the adoption by the Rural District Council of a proper code of building by-laws.

FROM the report of the roads and bridges committee of the Herefordshire County Council it appeared that the county surveyor (Mr. Jack) did not favour the tar-painting of the roads as a lasting success. He had lately seen some roads in Breconshire constructed under a new process, which affected the whole of the crust and not the surface only. There was no oil or tar in the process. He was much impressed with the appearance of the roads after much motor and other traffic. He was informed that the life was at least three years, and the cost from 1½*d.* to 2*d.* per yard over and above the cost of a water-bound road. If this were so it would be much more economical than tar. It could be laid down in any weather, and overcame the great difficulty of slipperiness, which were two very important considerations. The committee resolved to give no rural or urban districts consent to their tarring the roads.

A LOCAL Government Board inquiry was opened in the Workhouse, Castlerea, Ireland, by Mr. J. P. Hannigan, inspector, in connection with a scheme of the Castlerea Rural District Council for the erection of labourers' cottages, under the Labourers' Act, 1896, under the third improvement scheme. The number of applications for the erection of labourers' cottages was 182, and the estimated cost 32,494*l.* There were upwards of 100 objections by owners and occupiers of land to the erection of cottages on their lands. The Congested Districts Board objected in every case in which it was proposed to put a cottage on their lands, because they did not want the two Acts, which were passed for different purposes, brought into conflict.

AT the monthly meeting of the executive of the Edinburgh, Leith, and District Building Trades Association held at 61 Lothian Road recently, several members reported that during the past month they had had a good many inquiries for the purchase of property. The news was gladly received as being an indication that in the near future much of the property at present unoccupied would be taken up by investors. The present tendency is to hold up the property rather than sell at a loss, and as wages have remained the same during the past period of depression, while material has in some cases gone up in price, new property cannot be put up at the same price as the houses that are at present in the market. Altogether, in the new year builders are hopeful that better times are in store for them. Four new members were admitted to membership.

THE housing committee of the Liverpool Corporation have put down 10,000*l.* for the purchase and demolition of insanitary property on capital account. On capital account the committee require 30,000*l.* for buildings. The following note appears at the foot of the estimates:—"The housing committee desire to call the attention of the City Council to the fact that schemes under the Housing of the Working Classes Act, 1890, for dealing with six unhealthy areas and the erection of dwellings for the dispossessed, have been approved by the Local Government Board's provisional order. When the loans for carrying out the schemes in question are sanctioned by the Board, the housing committee propose to ask the Council for a supplementary estimate, in order that the work may be commenced as soon as possible. Meanwhile the acquisition of the various properties is being proceeded with."

BAKEWELL Urban District Council at their last meeting again had under consideration the plans for the proposed baths and pump room, as adopted a month or so ago. Messrs. Bryden & Walton, of Buxton, the architects, submitted alternative designs for the erection of a somewhat more attractive and imposing building than that contained in their original scheme, and after some discussion one of these was accepted, and it was resolved to submit same for the approval of his Grace forthwith. No alteration is contemplated in the internal arrangements, which provide for a swimming bath with sixteen collapsible dressing boxes, a pump room, &c. As soon as the plans are received back from the Duke of Rutland, a meeting of the Council will be held with a view to instructing the architects to get out the quantities, specifications, &c., as the necessary preliminary for obtaining tenders and the sanction of the Local Government Board.

THE Clyde Navigation Trustees have accepted the tender of the Clyde Structural Company, Ltd., for the erection of sheds for the west basin at Yorkhill, amounting to

16,877*l.* 13*s.* 11*d.* (being the lowest). Acceptance was also authorised of the offer of Messrs. Somervail & Co., Ltd., for the erection of four sheds at Prince's Dock Timber Storage at a total of 2,133*l.* (being the lowest). The traffic committee agreed to recommend the trustees to erect a single-storey shed, 1,370 feet long by 100 feet wide, along the Riverside Quay at Yorkhill at an estimated cost of 26,000*l.* This recommendation was adopted.

THE Tower of London will henceforward be lighted with municipal electricity supplied by the Stepney Borough Council, in whose statutory area it lies. For the past three years it has been supplied by the City of London Electric Lighting Company, with the permission of the Office of Works. The Council ascertained that even the representatives of the Crown are not legally empowered to dispense with the restrictions imposed upon the company by Act of Parliament. Proceedings are not available against the Crown authorities, having regard to the constitutional maxim that "the King can do no wrong." The Council commenced legal proceedings, but now the company has agreed to withdraw its supply.

MR. BANISTER FLETCHER commenced on January 11 a course of twelve lectures on the Renaissance Architecture of Germany, Belgium and Holland, Spain and England, at the London University, Imperial Institute Road, South Kensington, S.W. The lectures will be amply illustrated with lantern views and those historical events which have influenced the style will be discussed. The peculiar character of Continental Renaissance will be considered with reference to the principal buildings erected since A.D. 1500. The English Renaissance will include the Elizabethan and Jacobean styles, and the more important examples will be fully illustrated. The colleges of Oxford and Cambridge will be referred to, as well as the furniture and internal decoration. The later period includes the principal works of Inigo Jones and Sir Christopher Wren—St. Paul's, the City churches, Hampton Court, &c.—and the large number of country mansions erected during the Georgian period.

THE education committee and the York Corporation met specially on Monday to consider a report by the higher education sub-committee to the effect that the large hall of the Exhibition Buildings, which has for some years been largely used for concerts and various fêtes and functions, was unsafe and in danger of collapsing. Mr. W. H. Brierley, architect, stated in a report that the hall, which was erected for temporary purposes thirty years ago, had outlived the period during which it was intended to be used, and might collapse without any warning and should be taken down. A report was also read from the city surveyor (Mr. F. W. Spurr), suggesting the expenditure of a few hundred pounds in order to make the buildings last a few years longer. The large temporary hall of the buildings will accordingly be closed to the public at once.

THE Somerset County Council at their last meeting decided to apply to the Local Government Board for their consent to the borrowing by the County Council of the following sums for capital expenditure in respect of schools, the amounts to include costs attending the raising of the loans:—Elementary schools: Chard, High Street—new partitions, improvements to ventilation, infants' urinal, new fireplaces, and removal of galleries (borough of Chard and parish of Chard), amount 400*l.* Ilminster, Horton—new drainage, refitting offices, tar-paving, &c. (Ilminster and Ilminster Without), 200*l.* Ilminster, Ditton Street—new offices, drainage, tar-paving, &c. (Ilminster and Ilminster Without), 375*l.* West Bradley—refitting closets, improvements to drainage, asphalting playgrounds, &c. (West Bradley and East Pennard), 320*l.* Treborough—new classroom (Treborough), 200*l.* .Charlton Musgrove—enlargement of playground, new offices and partition (Charlton Musgrove), 365*l.* Woolavington—enlargement of classroom (Woolavington), 450*l.* Ashcott—site and new school buildings (Ashcott), 80*l.* and 1,500*l.* respectively.

various cases of instruments must exercise a great fascination to those about to buy. Messrs. Thornton will make to order special cases with any arrangement or style of instruments that may be selected. Their wallet pocket-cases are made in real morocco or in a cheaper leather. The manufacturers are constantly adding novelties and making improvements to the stock which has gained them the goodwill of architects, surveyors and draughtsmen of all kinds for over a quarter of a century.

MESSRS. REDPATH, BROWN & CO., LTD., have issued what may be regarded as an illustrated supplement to their free Handbook of Constructional Steelwork; for the pamphlet consists of single sheets of photographs showing steel structures and completed buildings for which they supplied the framework. The sheets are corded together and placed in a tasteful cover to which extra sheets may be added. The first three illustrations are of the steelwork for the Wallpaper Manufacturers' Works, Greenhithe. We notice that a New York architect was entrusted with this work. The Westminster Trust Buildings is an important block of eight storeys in Great Chapel Street, S.W. They are also supplying the steelwork for the Westminster Electric Power Station. Among the completed London buildings shown are the University College Hospital, the Scottish Provident Institution Buildings, Lombard Street; Harcourt House, the Cannon Street Fire Station, New Scotland Yard and United University Club. All the photographs are admirably reproduced and they testify to the important work which Messrs. Redpath, Brown & Co., Ltd., have carried out in London.

WE are reminded that the name of Willing has been closely associated with advertising for nearly forty years by the appearance of the thirty-sixth *Press Guide*. For the sum of one shilling the purchaser obtains a comprehensive index to the Press of the entire United Kingdom with concise particulars of their time and place of publication, price, features, &c. But this is only a part of the information crammed into its 450 pages. The range extends over Europe, the British Colonies, the United States and indeed literally from China to Peru.

WHAT THE PLUMBER SAW.

BY AN OCCASIONAL CORRESPONDENT.

HE was called to the house to do the usual little job, and was all over the house to find it. The "desirable residence" was of the usual modern semi-detached type with "every convenience" as part of its description. Possibly it had been awarded first prize in a competition organised by some technical journal in which the elevation with its pointed gables and Chinese-puzzle roof had appeared. The plumber had a vague recollection of seeing that picture on the other side of some paper which the office had once used when sending him the sizes and weights of some pieces of sheet lead. The house differed little from the usual house. Inside there were omissions and evidences of many afterthoughts; but the staircase had not been forgotten until the roof was on—which is saying something for the completeness of the plans. The external appearance, however, differed somewhat from the reproduction of the elevation the plumber had seen. This showed a sketch of a gentleman in an out-of-date tall hat standing at the gate, and a lady preceded by a child with a hoop coming down the garden walk. These were to "give life" to the picture. Perhaps the architect had put them there in reality when the house was first built, but they had left before the plumber arrived in search of the little job. The toy trees in the foreground, the rockery in the corner, and the mountain and woods in the background shown on the drawing were not there either. Still, these details apart, the house looked like its picture. Musing thus the plumber leisurely approached, followed by the usual boy carrying a bag containing the tools he was least likely to require.

Having got the general bearings of the house, position of the cellar, and ascertained the quality of the beer with a small dip pipe carried for the purpose, he began to seriously diagnose his job.

The gas jumped, the cylinder cupboard and the ceiling of the room below were wet, the hot water would not heat, the wash pipes and sanitary arrangements had a series of defects that were erratic in their periods and various degrees of inconvenience, and inexplicable in their cause.

The difficulty of the plumber's diagnosis was complicated owing to the pipes being as far as possible buried out of sight. The bricks had been chased, the plaster bulged, and there

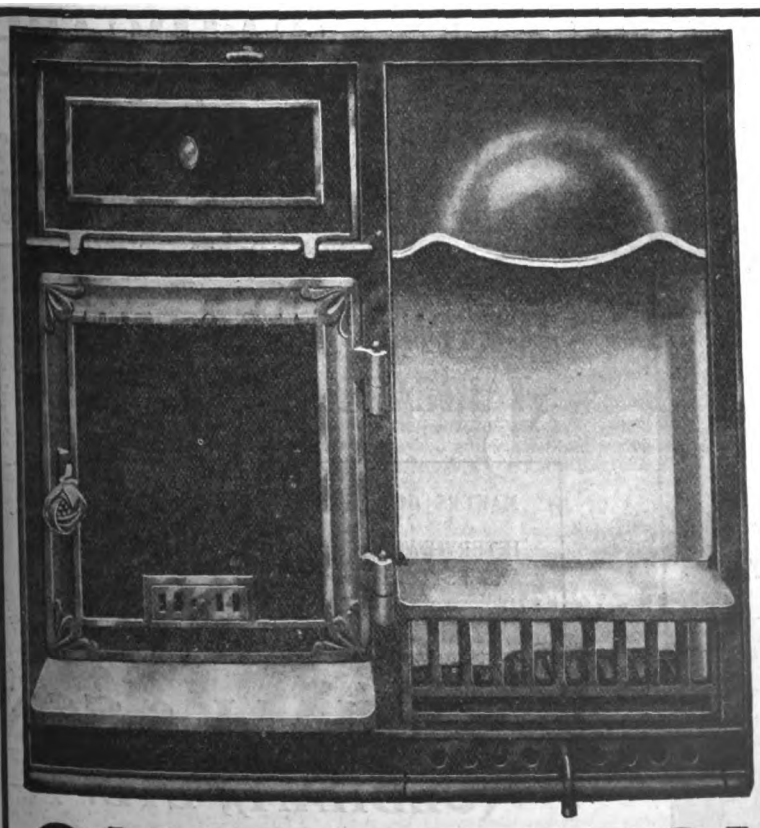
were evidences of almost frantic expedients lest a pipe should show.

The æsthetic tastes of the architect were primarily responsible for this condition, and his orders had proved the last persuasive argument for the sub-contractor plumber, who did the work, to abandon his intention of making a good job, despite the diminished profit such a resolution involved. Unfortunately the result did not place the responsibility on the architect, but upon the plumber and his fellow craftsmen generally. The gas meter and stopcock were the handiest, and therefore the first to be tackled, but in trying to turn off the tap, the difficulties commenced. The gas and meter had been one of the afterthoughts. Hence the only available position was one that assumed it would never require to be "got at" again after it was fixed. After a journey to the shop by the boy and one by the plumber himself, he got an eccentric tool which turned off the main supply cock, but broke the crutch in the process.



He then traced the regular festoons of the gas pipe under the cellar, and followed them under the other floors. To do this he broke holes through cellar and sleeper walls, thereby providing conveniences for future contingencies the architect had omitted. Except that in a general way it was all wrong, through the absence of wood strips on which to run the lead piping, the plumber had not yet found the exact cause of the jumps. He then got up the carpets and moved the furniture to find the gas board, under which the pipe should have run, unless the architect had pointed out some more erratic course. One of the boards was screwed, but the joiner had forgotten to cut off the tongues. So after considerable trouble and more journeys for tools, he reduced the board to matchwood, and split those immediately adjoining it. But there was no gas-pipe there.

The varied contents in the space between the ceiling and the boards would, if less common to the plumber, have been an interesting study. Dust and cobwebs galore and ample accommodation for vermin and parasites, with convenient means of ingress and egress and communication by means of the cavity walls to all parts of the building abundant. Wood shavings and other combustible materials were ready to help on the first fire. The plumber wondered why the architect (who in minor details showed evidence of his desire to provide for remote contingencies in cleanliness and ventilation) could find no cleaner way of constructing a floor than with this inaccessible catch place for filth and stale air.

As the day was getting on and the time was mounting up the plumber abandoned these reflections to pursue his search. On the way he found that a few nails had been driven into the lead gas-pipe by the mistress of the house to hang bric-à-brac and china on, and by the housemaid for other purposes, both using a flatiron to drive the points home. The plumber wondered in his clumsy way why lead and not iron had been used for the gas-pipes. Finally he found the moist place, let out the water and stopped the hole. The same thing would occur again in another place, though that was not his affair, but the architect's who originally specified the work and perhaps saw it done.

The hot-water trouble, or absence of that commodity, next engaged the plumber's attention and provided more scope for his imaginative genius to locate the trouble. The servant said the water had only become heated for a little time after the range had been newly set up, which information presupposed that the chimney-breast was not deep enough to accommodate the range, and the boiler flue was therefore ingeniously cut out of the party wall. This device had an advantage for at least a short time in so far as the fire heated the next door boiler, and in return the next door obliged with a few beetles, which came by the same way that the fire had travelled through the party wall. Of course the range and back boiler were afterthoughts, and the absence or curtailment of flue accommodation a too insignificant detail for the architect. The only remedy left for the plumber to propose was, "clean out underneath the boiler soon and often."

A contributory cause was provided by the convolutions of the lead circulating-pipes in their erratic course to reach the cylinder, the position of which, not being anticipated on the plan, was in the most inconvenient corner, with all its connections (which were made before the brickwork was built) at the back. The plasterer could not have plastered behind it even if he had remembered to do so. What the plumber saw round and about this made him wonder if the architect had ever anticipated that hot water might eventually be required when he drew the elevation. Before the

plumber completed this investigation he was informed that when the cylinder did by any chance get hot it danced to the accompaniment of very ominous throbbing and cracking sounds; so he tried to trace the pipes up to the caverns that he knew lay beneath the roof.

Having located the assumed direction of the pipes by dint of following the cracks in the wall paper and plaster, he essayed to get into the roof space. To do this required another journey to the shop for climbing tackle, and might have necessitated a specially made man or boy to get through the diminutive hole provided apparently for access. In keeping with other incongruities this so-called manhole was nowhere near the supply tank which formed the objective of the plumber's search, but it had the advantage of being out of casual observation. Having negotiated the hole and torn his trousers in that acrobatic feat, he commenced upon his journey, crawling under purlins and intersecting valley timbers, aided by the numerous rays of light which struggled through the defective tiling where the slater could not get in a tool small enough to point or get himself near enough to reach it. These little inconveniences were the penalties consequent upon the pointed gables and tricky dormers which made a picturesque elevation. The hungry chirp of several nests of young birds disturbed the silence of the caverns—they evidently thought the plumber was a luscious worm. The dust of the hairless mortar (which had been originally thrown up under the tiles to be shaken off by the wind) lay thick around, together with a liberal admixture of soot blown through the openings. The plumber saw revealed what had often been a source of mystery to the mistress—namely, where all the dust came from, and what made the laths show through the plaster on the bedroom ceilings. This caused him to wonder why this accommodation should be provided for soot and dust and occasional snow drifts with so little convenience for its prevention or removal. He had forgotten that this was all part of the penalty of that picture, of the sacrifice of internal comfort for external appearance. A flat roof would have been inartistic and out of the question.

Directed by the hissing of the ball-tap, the plumber wormed his way to the dark corner in which the supply tank was stored, having by this time put his foot partly through the ceiling owing to the uncertain light and position of the ceiling joists, there being no boards to walk on. He eventually arrived near the tank to find that necessities of the position prevented any investigation being conducted otherwise than at arm's length. He located the leak that was responsible for the two wet floors below, and as it was impossible to repair it without either removing the roof or the ceiling of the room below, he ingeniously adopted the temporary expedient of a putty and paint bandage, securing the whole with the usual piece of twine.

About this time a second boy arrived with a message that another job had come into the shop, so he prepared to leave the many other little matters he had seen, in the confident knowledge that his early return would be assured. The plumber wondered why water tanks and other things were put by the architect in such impossible positions, and why all the jokes in the comic papers and on the music-hall stage were confined to the plumber and his work.

What the plumber will see when he comes to repair the drains will create a still more intense degree of interest.

A BILL has been deposited for introduction into Parliament next Session under which it is proposed to incorporate a company by the name of the Harwich Docks Company. Upon this company it is sought to confer powers for the construction of a dock and two graving docks at Harwich in seven years. The capital is to be 1,650,000*l.*, with power to borrow a further sum of 550,000*l.*

THE Gloucestershire County Council have adopted plans for the extension of the Shire Hall so as to bring all the county departments into one building, subject to the approval of the education committee. The committee entrusted with the matter will advertise for tenders for the carrying out of the work.

THE Bournemouth Borough Council last week approved of a scheme for the erection of a Kursaal on the site of the Belle Vue Hotel. Plans are to be prepared for a pavilion, to include a large assembly room, small hall, lounge, smoking room, reading and billiard rooms, restaurant, dining room, &c., at the estimated cost of 45,000*l.*

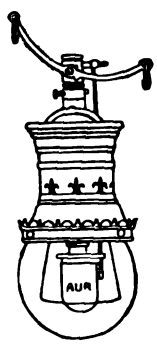
Welsbach
Light and Heat

A 70 Candle power Light



British Made

No. 5119a. This is another pattern of miniature Arc Lamp, specially designed for more exposed Lobby Lighting. Like No. 5120, shown opposite, it is draught and dust proof. Gas consumption, about 4 ft. per hour. Lamp, 80 candle power, price 6s. By-pass 2s. extra.

For 3 feet of Gas per hour

British Made

No. 5120. The Welsbach "Aurora" Lamp, an exceedingly pretty miniature Inverted Arc Lamp, draught and dust proof, for Lobbies and Halls, 80 candle power for 4 ft. of gas per hour. Price, Brass, 5s. Porcelain instead of brass body, 5s. 6d. By-pass 2s. extra.

The Welsbach Inverted Burner.

This latest and most artistic design in Inverted Burners, introduced late last season by the Welsbach Company, represents the perfecting of the system of inverted lighting. It is fitted with Welsbach Gas and Air Regulators, which do away with inequalities of gas pressure and ensure a steady light of the true soft Welsbach quality. This burner, guaranteed to be satisfactory, is free from the vexations attending many types of inverted burners, and has already made inverted lighting more popular than ever. It gives more light at less cost than any other type of inverted burner—70 candle power for less than 3 feet of gas per hour.

PRICE: Burner only, 4s. Complete with Mantle and Globe, as shown, 4s. 10½d. Gem size or Bijou size, burner only, 3s.
The Welsbach Mantles for Upright Burners are "C," "CX," and "Plaissetty," 4½d. each. Inverted Mantles, 6d. each.

Welsbach-Kern Radiators for heating scientifically — and economically. —

RADIATOR O.J. Fitted with five tubes; suitable for a room 12 ft. square. Height 17 in., width 12 in. Finished in art black. Price 30s. Top to lift off with boiling ring attachment for kettle, 6s. extra.

The Welsbach Radiators are gas fires with the important difference of being just as cheerful and just as healthy as coal fires, without the dust and without the work. They mark a distinct advance in gas heating, and heat a room more efficiently and at a lower cost than in any other way. They are inexpensive, and last a life-time. Made in 30 models to suit rooms up to 30 ft. square. See also Welsbach "Renown" Gas-heated Steam Radiators, for heating Churches, Institutions, Factories, &c.

The "LANCET" says:
"We doubt whether such an out-put of radiant heat has ever before been attained at so little cost and so low an expenditure of gas. The Welsbach-Kern Radiators give a cheerful, *healthy*, radiant heat, and are remarkably economical."

There is no waiting to burn up. The heat is there quickly, just when wanted.

Facts and figures about any kind of lighting, and Catalogues and descriptive booklets of Welsbach Light and Heat for all — purposes, will be forwarded post free on application to —

RADIATOR No. O.D. Fitted with five tubes. Suitable for a room about 12 ft. square. Height 16 in., width 14½ in. Finished in art black. Price 30s.

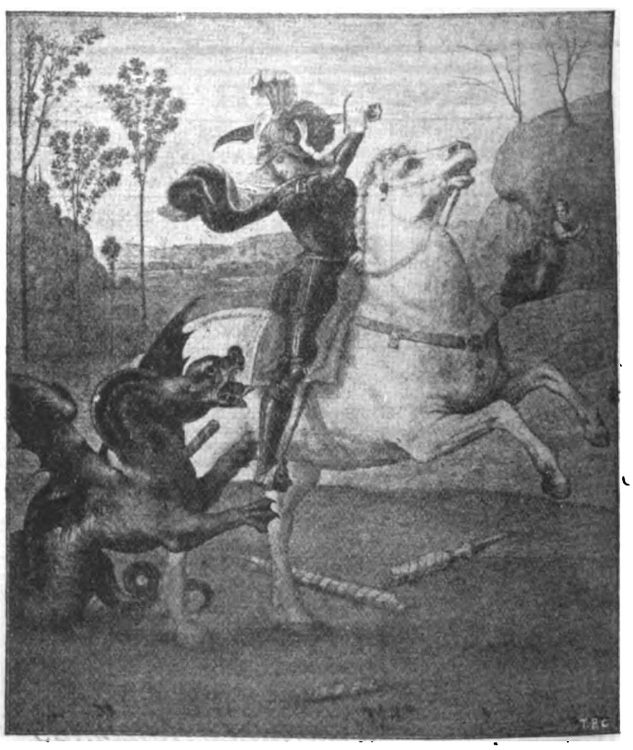
Art Plates from "The Architect."

AWARDED GOLD MEDALS, INTERNATIONAL HEALTH EXHIBITION AND ARCHITECTURAL AND BUILDING TRADES EXHIBITION (1889).

PROOFS on PLATE PAPER of the following Illustrations which have appeared in "THE ARCHITECT" can now be obtained in a separate form on proof paper suitable for framing.

***The Corn Field.*—(1) Ploughing; (2) Harrowing; (3) Mowing; (4) Carting; (5) The Products of the Corn Field.**

In Five Separate Plates. Total Length, 14 ft. 7 in. by 15 in. deep. A splendid example of Colour Work in Permanent Ink Photo. By M. PAUL ALBERT BAUDOIN. This magnificent Illustration was presented to the Subscribers to "THE ARCHITECT," in 1886. A few proofs were taken which immediately became out of print.



OPINIONS OF THE PRESS.—"We are not surprised to hear that there has been a great demand for the beautiful reproductions of the well-known frieze by M. Paul Albert Baudoin, entitled 'The Corn Field.' The plates have been reproduced by subscription at half a guinea the set, and so great has been their success that a second edition has been issued."—*The Lady's Pictorial.* "They are beautifully done in colours by the permanent ink-photo process and form a very artistic and pleasing set at the extremely moderate price of half a guinea."—*The Stage.* "The well-known frieze entitled 'The Corn Field,' which is a splendid example of colour work in permanent ink photo by M. Paul Albert Baudoin, is to be reproduced by subscription of half a guinea a set. They are exceedingly artistic and would grace the walls of any house."—*The Gentlewoman.* AND NUMEROUS OTHERS.

In consequence of the almost daily demand for these Plates they have been reproduced by Subscription at Half a Guinea the Set, free by post, carefully packed inside patent roller, and are now ready for issuing. Immediate application is requested. May be had framed in Black Reeded Frame with Gold Mounts, price Three Guineas the Set of Five Pieces.
